GSP. Additionally, as set forth in Water Code section 10720.5(a) any GSP adopted pursuant to this Agreement shall be consistent with Section 2 of Article X of the California Constitution and nothing in this Agreement modifies the rights or priorities to use or store groundwater consistent with Section 2 of Article X of the California Constitution . . . Likewise, as set forth in Water Code section 10720.5(b) nothing in this Agreement or any GSP adopted pursuant to this Agreement determines or alters surface water rights or groundwater rights under common law or ay provision of law that determines or grants surface water rights."); 180/400-Foot Aquifer Subbasin GSP, p. 9-10 ("This GSP is part of an integrated plan for managing groundwater in all six subbasins of the Salinas Valley Groundwater Basin that are managed by the SVBGSA. The projects and management actions described in this GSP constitute an integrated management program for the entire Valley."); *id.* at 10-14 ("The SVBGSA oversees all or part of six subbasins in the Salinas Valley Groundwater Basin. Implementing the 180/400-Foot Aquifer Subbasin GSP must be integrated with the implementation of the five other GSPs in the Salinas Valley Groundwater Basin . . . The implementation schedule reflects the significant integration and coordination needed to implement all six GSPs in a unified manner."); see also Draft Upper Valley GSP, p. 10-16; Draft Eastside Subbasin GSP, pp. 9-1, 10-7, 10-8, 10-16; Draft Forebay Subbasin GSP, pp. 2-4, 9-2, 9-4, 10-7, 10-9, 10-17; Draft Langley Subbasin GSP, pp. 2-4, 9-1, 9-4, 10-8, 10-9, 10-16.

water budget was created using the Salinas Valley Integrated Hydrologic Model (SVIHM).[14] The draft GSPs for the Eastside, Langley, Forebay, and Upper Valley Subbasins take a different approach—the historical and current water budgets were developed using a "provisional version" of the SVIHM, while future water budgets were developed using "an evaluation version" of the Salinas Valley Operational Model (SVOM).[15] And the draft Monterey Subbasin GSP utilizes a third approach—employing the Monterey Subbasin Groundwater Flow Model for the historic, current, and projected water budgets.[16]

What is more, each of these approaches uses different time periods: (1) the 180/400-Foot Aquifer Subbasin GSP analyzes a historical period of 1995 to 2014 and a current period of 2015 to 2017[17]; (2) the draft GSPs for the Langley, Eastside, Forebay, and Upper Valley Subbasins analyze a historical period of 1980 through 2016 and a current period of 2016[18]; and, (3) the draft Monterey Subbasin GSP analyzes a historical period of 2004 to 2018 and a current period of 2015 to 2018.[19]

The inconsistency in the water-budget approaches for each subbasin must be addressed in the draft GSPs. Absent such an analysis, the draft GSPs cannot adequately analyze a subbasin's potential to impact an adjacent subbasin or foster integrated groundwater management throughout the Basin.[20] Further, this absence of analysis prevents informed input on the draft GSPs by interested parties.[21]

This issue is best exemplified in the inconsistencies between the 180/400-Foot Aquifer Subbasin GSP and the draft Forebay Subbasin GSP. The 180/400-Foot Aquifer Subbasin GSP estimates that the 180/400-Foot Aquifer Subbasin receives (historically and currently) 17,000 acre-feet per year (AFY) of subsurface flow from the Forebay Subbasin.[22] However, the draft Forebay Subbasin GSP estimates that this amount was 3,100 AFY historically and 2,900 AFY currently. These numbers in the draft Forebay GSP are likely

[14] 180/400-Foot Aquifer Subbasin GSP, p. 6-1.
[15] See each referenced draft GSP, pp. 6-1-2. The GSA's use of the SVIHM and SVOM models for the draft GSPs does not satisfy the modeling requirements in the GSP Regulations. Section 352.4(f) of the GSP Regulations state that the models used to develop GSPs must "include publicly available supporting documentation" and "consist of public domain open-source software." The GSPs acknowledge that these requirements are not satisfied, and the draft GSPs state that "[d]etails regarding source data, model construction and calibration, and results for future budgets will be summarized in more detail once the model and associated documentation are available." (See, e.g., Draft Upper Valley Aquifer Subbasin GSP, pp. 6-1-2.) Interested parties cannot provide informed comments and input on the draft GSPs until the GSAs incorporate use of models that satisfy the GSP Regulations.
[16] Draft Monterey Subbasin GSP, p. 6-7.
[17] 180/400-Foot Aquifer Subbasin GSP, p. 6-1.
[18] See each referenced draft GSP, pp. 6-7-8.
[19] Draft Monterey Subbasin GSP, p. 6-5.
[20] See DWR, Water Budget BMP, p. 9 ("Building a coordinated understanding of the interrelationship between changing water budget components and aquifer response will allow local water resource managers to effectively identify future management actions and projects most likely to achieve and maintain the sustainability goal for the basin.").
[21] The draft GSPs also do not explain why different years are used to set minimum thresholds and measurable objectives in each subbasin, or how those inconsistencies impact sustainable groundwater management. (See aguilogic, Inc. Memo, p. 3, attached hereto as **Exhibit A**.)
[22] 180/400-Foot Aquifer Subbasin GSP, p. 6-16.

overestimates (i.e., the 180/400-Foot Aquifer is estimated to receive less subsurface flow from the Forebay Subbasin than the stated numbers) as the SVIHM utilized to provide the estimates in the draft Forebay Subbasin GSP only accounted for approximately 65% of the groundwater pumping in the Forebay Subbasin.[23] The discrepancy in interbasin flow needs to be addressed in the draft Forebay Subbasin GSP, or identified as a data gap that will be addressed through additional modeling as soon as possible. Without such information, the draft GSP cannot analyze how its implementation will impact the implementation of the 180/400-Foot Aquifer Subbasin GSP.

In sum, the draft GSPs must identify and analyze the inconsistencies in the modeling simulations and the time periods used for the water budgets in each of the GSPs in order to satisfy SGMA.[24] The *Alliance* identified a potential solution to this issue in its correspondence to the SVBGSA dated August 12, 2021, wherein the *Alliance* requested that the GSA conduct additional simulations with the SVIHM that are specifically focused on the issue of interbasin groundwater flows in order to understand the amount of Basin-wide groundwater discharge that is and has been captured by pumping. After adjusting the modelling simulations with GEMS data, the SVBGSA could integrate the data into the draft GSPs and provide an informed analysis of how each draft GSP will impact adjacent subbasins. Based upon the text of the draft GSPs, it appears that this modelling has already been completed in some capacity. In each of the draft GSPs for the Langley, Eastside, Forebay, and Upper Valley Subbasins, the GSPs state a “model simulation without any groundwater pumping in the model . . . was compared to the model simulation with groundwater pumping” to understand depletion of interconnected surface water.[25] However, the draft GSPs do not extrapolate this data to analyze impacts on surface or subsurface interbasin flows or adjacent subbasins. The *Alliance* understands that the SVBGSA is undertaking additional modeling for an update to the draft GSPs and strongly recommends that the SVBGSA incorporate the *Alliance’s* requested modeling simulations into the update. If not, the *Alliance* urges the SVBGSA to commit to adding this information prior to adoption of the draft GSPs or committing to a timeline in which it will be added shortly thereafter. Without this information, the GSPs cannot not analyze each of the issues required to be addressed by SGMA.

B. The Draft GSPs Do Not Adequately Analyze Impacts to Adjacent Subbasins

As discussed above, a GSP must not adversely affect “the ability of an adjacent basin to implement their [GSP] or impede[] achievement of sustainability goals in an adjacent basin.”[26] The GSP Regulations specify that minimum thresholds should be selected to “avoid causing undesirable results in adjacent basins or affecting the ability of adjacent basins to achieve sustainability goals.”[27] And the GSP Regulations require DWR to evaluate a GSP to ensure it satisfies these objectives.[28] The draft GSPs as currently presented do not satisfy these requirements.

[27] GSP Regs., § 354.28(b)(3).
[28] GSP Regs., § 355.4(b)(7).

1. The Draft Eastside Subbasin and Langley Subbasin GSPs

The Eastside Subbasin and Langley Subbasin GSPs largely require similar analysis and information to satisfy SGMA. The GSPs do not account for impacts to adjacent subbasins in defining sustainable yields or setting minimum thresholds and measurable objectives. Each of these issues is addressed in detail below.

a. *The GSPs do not account for impacts to adjacent subbasins in defining sustainable yields*

SGMA defines "sustainable yield" as "the maximum quantity of water, calculated over a base period representative of long-term conditions in the basin and including any temporary surplus, that can be withdrawn annually from a groundwater supply without causing an undesirable result."[29] Further, the sustainable yield must be defined in a manner that will not result in undesirable results in adjacent subbasins.[30] Here, the sustainable yields in the draft GSPs for both the Eastside and Langley Subbasins do not account for impacts on interbasin flow to the 180/400-Foot Aquifer Subbasin.

For example, the draft Eastside Subbasin GSP states that a pumping depression east of the City of Salinas creates a hydraulic gradient towards the depression, with groundwater flowing towards the pumping depression and away from the boundary with the 180/400-Foot Aquifer Subbasin.[31] This depression has reversed the natural downgradient groundwater flow from the Eastside Subbasin to the 180/400-Foot Aquifer Subbasin, drawing 3,600 AFY historically and 5,400 AFY currently of groundwater from the 180/400-Foot Aquifer Subbasin.[32] This amount is likely substantially underestimated as the SVIHM only accounts for 81% of groundwater pumping in the Subbasin.[33] Despite this unnatural hydraulic gradient and the pull of groundwater from the 180/400-Foot Aquifer Subbasin, the draft Eastside Subbasin GSP includes this interbasin flow in its calculation of sustainable yield,[34] but the draft GSP does not analyze how estimated sustainable yield will impact groundwater management in the 180/400-Foot Aquifer Subbasin.

Similarly, the draft Langley Subbasin GSP states that a pumping depression has formed in the center of the Langley Subbasin as a result of a pumping trough.[35] Groundwater is drawn towards the pumping depression and away from the 180/400-Foot Aquifer Subbasin despite the natural downward gradient flow towards the 180/400-Foot Aquifer and Eastside Subbasins.[36] The draft Langley Subbasin GSP then estimates that,

[29] Wat. Code, § 10721(w).
[30] See Wat. Code, § 10733.
[31] Draft Eastside Subbasin GSP, p. 5-11.
[32] *Id.* at pp. 6-19-20 ("Groundwater pumping near the [C]ity of Salinas has created a cone of depression . . . that draws in groundwater into the Eastside Aquifer Subbasin from the 180/400-Foot Aquifer Subbasin, which is naturally slightly downgradient in the Salinas area. Estimated groundwater inflows from the 180/400-Foot Aquifer Subbasin have slightly increased since 1980.").
[33] *Id.* at p. 6-17. The 180/400-Foot Aquifer Subbasin GSP estimates the outflow to the Eastside and Langley Subbasins amounts to 8,000 AFY. (*Id.* at p. 6-19.)
[34] *Id.* at pp. 6-22-24, Table 6-10.
[35] Draft Langley Subbasin GSP, p. 5-7.
[36] *Id.* at p. 5-18, Figure 5-11.

despite this reversal in groundwater elevations, the 180/400-Foot Aquifer Subbasin has historically received 3,700 AFY and currently receives 2,900 AFY in interbasin flow from the Langley Subbasin, while the Eastside Subbasin has historically received 1,100 AFY and currently receives 1,700 AFY in interbasin flow from the Langley Subbasin.[37] However, the draft Langley Subbasin GSP fails to analyze how the pumping depression in the Langley Subbasin has impacted and will continue to impact these interbasin flows—e.g., what are the outflows to the 180/400-Foot Aquifer and Eastside Subbasins if the pumping depression were ameliorated? Again, the draft GSP includes these unnatural interbasin flows in its calculation of the sustainable yield without analyzing the impacts on adjacent subbasins.[38]

Without understanding how groundwater production impacts interbasin flows, the draft GSPs cannot accurately estimate the sustainable yield of the subbasins and their impact on adjacent subbasins.[39] As discussed above, this issue can be addressed by undertaking the additional modeling simulations requested by the *Alliance* and revising the draft GSPs accordingly. This additional information should be added prior to the adoption of the draft GSPs, or the draft GSPs should commit to a timeline under which this information will be added as soon as possible after adoption of the draft GSPs.

b. *The GSPs do not analyze how their minimum thresholds and measurable objectives will impact adjacent subbasins*

The draft GSPs also do not consider impacts to adjacent subbasins in their setting of minimum thresholds and measurable objectives, as required by SGMA.[40]

For example, the draft Eastside Subbasin GSP sets the minimum threshold for groundwater elevations at 2015 levels.[41] As shown in Figure 8-1, these levels are only nominally above historic lows (approximately 6 feet higher) and barely above the lowest elevation since the introduction of the CSIP and Salinas Valley Water Project.[42] Consequently, these groundwater elevations will still produce a significant pumping

---

[37] *Id.* at p. 6-19.
[38] *Id.* at pp. 6-21-23.
[39] See DWR Water Budget BMP, p. 17 (To evaluate the impact on adjacent basin, "this will necessitate GSA coordination and sharing of water budget data, methodologies, and assumptions between contiguous basins including: • Accurate accounting and forecasting of surface water and groundwater flows across the basin boundaries.").
[40] GSP Regs., § 354.28(b)(3) ("The description of minimum thresholds shall include the following: . . . (3) How minimum thresholds have been selected to avoid causing undesirable results in adjacent basins or affecting the ability of adjacent basins to achieve sustainability goals."); see also GSP Regs., § 355.4(b)(7); DWR Sustainable Management Criteria BMP, p. 9; DWR Sustainable Management Criteria BMP, p. 10 ("The purpose of the specific requirements is to ensure consistency within groundwater basins and between adjacent groundwater basins.").
[41] Draft Eastside Subbasin GSP, p. 8-7.
[42] *Id.* at p. 8-13.

depression east of the City of Salinas that will draw water away from the boundary with the 180/400-Foot Aquifer Subbasin.[43]

Similarly, the draft Langley Subbasin GSP sets the minimum threshold for groundwater elevations at 2019 levels—the lowest elevations since the introduction of the CSIP and Salinas Valley Water Project and only nominally above the historic lows in the Subbasin.[44] These levels will continue to produce a significant pumping depression east of the City of Salinas that will draw water away from the boundary with the 180/400-Foot Aquifer Subbasin.[45] Despite the maintenance of these unnatural gradients, neither draft GSP analyzes how these minimum thresholds will impact adjacent subbasins (e.g., the 180/400-Foot Aquifer Subbasin).

The draft GSPs for the Eastside and Langley Subbasins merely include the statement that: "Minimum thresholds for the [subbasins] will be reviewed relative to information developed for the neighboring subbasins' GSPs to ensure that these minimum thresholds will not prevent the neighboring subbasins from achieving sustainability."[46] This statement is not evidence and it does not ensure the management of the subbasins will avoid impacts to adjacent subbasins.[47] As discussed above, this issue can be addressed by undertaking the additional modeling simulations requested by the *Alliance* and revising the draft GSPs accordingly.

The lack of analysis is concerning as both draft GSPs acknowledge that low groundwater elevations within the Langley and Eastside Subbasins may exacerbate seawater intrusion in the 180/400-Foot Aquifer Subbasin.[48] But the draft GSPs only mention this issue in concluding: "The chronic lowering of groundwater

---

[43] *Id.* at p. 8-10, Figure 8-3. The same issue applies to the draft Eastside Subbasin GSP's measurable objective for groundwater elevations—it maintains a pumping depression that reverses the natural hydraulic gradient towards the 180/400-Foot Aquifer Subbasin but fails to explain how the measurable objective will not impact the 180/400-Foot Aquifer Subbasin. (See e.g., Draft Eastside Subbasin GSP, p. 8-19.)
[44] Draft Langley Subbasin GSP, pp. 8-8, 8-13.
[45] *Id.* at p. 8-10. Again, the same issue applies to the draft Langley Subbasin GSP's measurable objective for groundwater elevations—it maintains a pumping depression that reverses the natural hydraulic gradient towards the 180/400-Foot Aquifer Subbasin but fails to explain how the measurable objective will not impact the 180/400-Foot Aquifer Subbasin. (See e.g., Draft Langley Subbasin GSP, p. 8-19.)
[46] *Id.* at p. 8-6; Draft Eastside Subbasin GSP, p. 8-16.
[47] See Joint Exercise of Powers Agreement Establishing the SVBGSA, § 4.3 ("As set forth in Water Code section 10723.3, the GSA shall consider the interests of all beneficial uses and users of groundwater in the Basin, as well as those responsible for implementing the GSP. Additionally, as set forth in Water Code section 10720.5(a) any GSP adopted pursuant to this Agreement shall be consistent with Section 2 of Article X of the California Constitution and nothing in this Agreement modifies the rights or priorities to use or store groundwater consistent with Section 2 of Article X of the California Constitution . . . Likewise, as set forth in Water Code section 10720.5(b) nothing in this Agreement or any GSP adopted pursuant to this Agreement determines or alters surface water rights or groundwater rights under common law or ay provision of law that determines or grants surface water rights.").
[48] See Draft Langley Subbasin GSP, pp. 3-18, 4-32, 5-18 (Figure 5-11 "shows the groundwater elevations that are persistently below sea levels that, when paired with a pathway, enable seawater intrusion. The groundwater elevation contours show that groundwater is drawn toward the depression at the northern end of the Eastside Aquifer Subbasin. If the magnitude of this depression increases, it could potentially draw seawater intrusion into the Langley Subbasin."), 5-20 (Figure 5-11); Draft Eastside Subbasin GSP, pp. 3-17,

level minimum thresholds are set above historic lows. Therefore, the groundwater elevation minimum thresholds are intended to not exacerbate, and may help control, the rate of seawater intrusion."[49] That statement must be revised to acknowledge that the pumping depressions in the Langley and Eastside Subbasins will remain even if the groundwater elevation minimum thresholds and measurable objectives are achieved, and the seawater minimum thresholds set by the draft Langley and Eastside Subbasin GSPs only protect against seawater intrusion in their respective subbasins, not against seawater intrusion in adjacent subbasins like the 18/400-Foot Aquifer Subbasin.[50]

In sum, the draft Langley and Eastside Subbasin GSPs in their current form do not account for potential impacts to adjacent subbasins in setting their minimum thresholds and measurable objectives. As a result, the draft GSPs cannot provide any evidence that their implementation will not impair implementation of a GSP in an adjacent subbasin—e.g., the 180/400-Foot Aquifer Subbasin GSP's seawater intrusion minimum threshold, which requires seawater intrusion to be maintained at 2017 levels, and measurable objective, which requires the seawater intrusion isocontour to be pushed back to Highway 1.[51] This analysis should be added to the draft GSPs prior to adoption by the SVBGSA, or the draft GSPs should provide a commitment to incorporating this information within a time certain.[52]

c. *There is no support for using groundwater elevations as a proxy for groundwater storage minimum thresholds*

As mentioned above, the sustainable yield of the basin is the amount of water that can be withdrawn annually without causing an undesirable result, such as the "significant and unreasonable reduction of groundwater storage."[53] The GSP Regulations permit a minimum threshold for groundwater elevations to be used as the minimum threshold for other sustainability indicators, "where the Agency can demonstrate that the representative value is a reasonably proxy . . . as supported by adequate evidence."[54] Here, both the draft Eastside Subbasin GSP and the Langley Subbasin GSP utilize groundwater elevation minimum thresholds

---

4-35 ("the groundwater elevations in the northwestern portion of the Eastside Subbasin (near the City of Salinas) are below sea level, creating a groundwater gradient away from the coast and towards the Eastside Subbasin"), 5-26-29 .

[49] Draft Langley Subbasin GSP, p. 8-15; Draft Eastside Subbasin GSP, p. 8-15.

[50] Draft Langley Subbasin GSP, p. 8-28; Draft Eastside Subbasin GSP, p. 8-29.

[51] See 180/400-Foot Aquifer Subbasin GSP, pp. 8-32-37.

[52] A report prepared for MCWRA has highlighted the significant impact pumping in the Eastside and Langley Subbasins has on seawater intrusion in the 180/400-Foot Aquifer Subbasin. (See November 19, 2013, Technical Memorandum, Protective Elevations to Control Sea Water Intrusion in the Salinas Valley, attached hereto as **Exhibit D**.) The report states: "At one time (before excessive pumping), the East Side Subarea was one of the natural sources of recharge to the adjacent Pressure Subarea with ground water flowing from the northeast to the southwest. However, historical groundwater level declines have resulted in a reversal of the gradient." (*Id.* at p. 3.) The report then states that: "Artificial recharge in the East Side Subarea would reduce subsurface inflow from the Pressure Subarea and eventually restore the historical northeast to southwest recharge. Both northwest underflow from the Forebay Subarea as well as southwest recharge from the East Side Subarea would help control seawater intrusion." (*Id.* at pp. 6-7.) See also aquilogic Memo, pp. 8-12, attached hereto as **Exhibit A**.

[53] Wat. Code, § 10721(w), (x).

[54] GSP Regs., § 354.28(d); DWR Sustainable Management Criteria BMP, pp. 17-18.

as proxies for groundwater storage minimum thresholds.[55] However, there is insufficient evidence to support that approach.

In particular, each of the draft GSPs sets groundwater elevations at near historic lows, and show a substantial trend in declining groundwater storage over the historic period.[56] The minimum threshold groundwater elevations, in other words, have resulted in overdraft of the subbasins.[57] And by setting the minimum thresholds at historic low groundwater elevations, the draft GSPs will facilitate continued decline in groundwater storage.[58] In fact, because there is no commitment to pump at the sustainable yield of the subbasins, it is possible that production in the subbasins could increase over historic and current amounts so long as the subbasins do not experience another significant drought and still comply with the groundwater elevation minimum thresholds. The SVBGSA's prior actions seem to imply that utilizing groundwater elevations as a proxy in this scenario is improper—the 180/400-Foot Aquifer Subbasin GSP set the groundwater storage minimum threshold to production at the projected sustainable yield.[59] The draft GSP must explain why this different approach will suffice now.

2. The Draft Forebay and Upper Valley Subbasin GSPs

The draft Forebay and Upper Valley Subbasin GSPs lack the same analysis as the draft GSPs for the Eastside and Langley Subbasins—they do not adequately consider impacts to adjacent subbasins. These issues begin with the draft GSPs' water budget and estimate of sustainable yield, and cascade through the minimum thresholds, measurable objectives, and projects and management actions.

As discussed above, SGMA requires GSPs to define a sustainable yield for each basin that will avoid undesirable results and impacts to adjacent basins. The sustainable yields defined in the draft GSPs for the Forebay and Upper Valley Subbasins do not meet this threshold. Both draft GSPs conclude that the subbasins have not been in overdraft historically, but they do not analyze how groundwater pumping within the subbasins (151,100 to 174,500 AFY in the Forebay Subbasin and 108,500 to 129,600 AFY in the Upper Valley) impacts surface and subsurface flows to adjacent subbasins.[60]

---

[55] Draft Eastside Subbasin GSP, p. 8-23; Draft Langley Subbasin GSP, p. 8-22.
[56] See discussion *supra;* Draft Eastside Subbasin GSP, p. 5-21; Draft Langley Subbasin GSP, p. 5-16.
[57] *Ibid*.
[58] See, e.g., Wat. Code, § 10721(x)(1) ("Overdraft during a period of drought is not sufficient to establish a chronic lowering of groundwater levels if extractions and groundwater recharge are managed as necessary to ensure that reductions in groundwater levels or storage during a period of drought are offset by increases in groundwater levels or storage during other periods.").
[59] 180/400-Foot Aquifer Subbasin GSP, p. 8-25 ("The total volume of groundwater that can be annually withdrawn from the Subbasin without leading to a long-term reduction in groundwater storage or interfering with other sustainability indicators is the calculated sustainable yield of the Subbasin."); see also DWR GSP Assessment Staff Report, p. 25 ("The Plan describes how setting the minimum threshold as the long-term sustainable yield for the Subbasin is a reasonable, protective approach against overdraft and the long-term reduction of groundwater storage.").
[60] Draft Forebay Subbasin GSP, pp. 6-45-46; Draft Upper Valley Subbasin GSP, pp. 6-22-23.

For example, the draft Forebay Subbasin GSP states that the SVIHM, which undercounts groundwater pumping by 35%, estimates the Forebay Subbasin received 90,300 AFY historically through stream exchange, currently receives 77,800 AFY, and 31,800 AFY of that stream exchange on average is caused by groundwater pumping.[61] Similarly, the draft Upper Valley Subbasin GSP states that the SVIHM, which under counts groundwater pumping by 24%, estimates the Upper Valley Subbasin received 89,100 AFY historically through stream exchange, currently receives 65,500 AFY, and 1,100 AFY of that stream exchange on average is caused by groundwater pumping.[62] This recharge is substantially induced by the operation of the Nacimiento and San Antonio Reservoirs; prior to that time groundwater storage was significantly decreasing in the subbasins.[63] However, neither draft GSP analyzes: (a) how streamflow recharges the subbasins during drought years, offering instead averages over the historical period, and (b) how groundwater pumping impacts natural surface or subsurface flows to adjacent subbasins—i.e., without pumping, how much groundwater would flow to the downgradient subbasin? Instead, the draft GSPs use the average stream exchange amounts to facilitate a "finding" that the subbasins are presently managed within their sustainable yield. Without understanding how pumping impacts streamflow during drought years and interbasin surface and subsurface flow, the draft GSPs cannot reasonably estimate sustainable yield in the subbasins or analyze how implementation of the draft GSPs will impact adjacent subbasins' GSPs.

The failure to analyze impacts to adjacent subbasins becomes more apparent in the draft GSPs' discussion of minimum thresholds. The draft Forebay Subbasin GSP sets the minimum threshold for groundwater elevations at 2015 groundwater levels, only a few feet above the historic low, while the draft Upper Valley Subbasin GSP sets the minimum threshold for groundwater elevations at "5 feet <u>below</u> the lowest ground elevation between 2012 and 2016," significantly below the historic low.[64] These minimum thresholds are not reasonable—set at levels experienced at the bottom of a historic drought, or even lower—and cannot be qualified as sustainable groundwater management.[65] The draft Upper Valley GSP admits as much, stating: "The groundwater elevations during the 2012 to 2016 drought in the Upper Valley Aquifer Subbasin are the lowest groundwater elevations seen in the Subbasin and are considered <u>significant and unreasonable</u>."[66]

---

[61] Draft Forebay Subbasin GSP, pp. 5-30, 6-23. Note that the draft GSPs may also underestimate streamflow depletion by only analyzing stream cells that are connected to groundwater more than 50% of the time. (See aquilogic Memo, p. 5, attached hereto as **Exhibit A**.)
[62] Draft Upper Valley Subbasin GSP, pp. 5-31, 6-22.
[63] Draft Upper Valley Subbasin GSP, p. 5-18; Draft Forebay Subbasin GSP, p. 5-17; see also Hydrogeology and Water Supply of Salinas Valley, pp. 15-16, attached hereto as **Exhibit D**.
[64] Draft Forebay Subbasin GSP, pp. 8-8, 8-14; Draft Upper Valley Subbasin GSP, pp. 8-7, 8-12 (emphasis added).
[65] Wat. Code, § 10720.1 ("In enacting this part, it is the intent of the Legislature to do all of the following: (a) To provide for the sustainable management of groundwater basins. . . . (c) To establish minimum standards for sustainable groundwater management."]; GSP Regs., § 355.4(b) ("When evaluating whether a Plan is likely to achieve the sustainability goal for the basin, the Department shall consider the following: (1) Whether the assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are reasonable and supported by the best available information and best available science. . . .").
[66] Draft Upper Valley Subbasin GSP, p. 8-10 (emphasis added).

Moreover, the draft GSPs do not analyze how the minimum thresholds will impact flows in the Salinas River or adjacent subbasins. Rather, this analysis appears to be deferred to the future. The draft GSPs state that: "Minimum thresholds . . . will be reviewed relative to information developed for neighboring subbasins' GSPs to ensure that these minimum thresholds will not prevent the neighboring subbasin from achieving sustainability."[67] As discussed above, this issue can be addressed by undertaking the additional modeling simulations requested by the *Alliance* and revising the draft GSPs accordingly. This additional information should be added prior to the adoption of the draft GSPs, or the draft GSPs should commit to a timeline under which this information will be added as soon as possible after adoption of the draft GSPs.

These same concerns are raised with respect to the groundwater storage minimum thresholds. The draft Upper Valley Subbasin GSP uses the groundwater elevation minimum threshold as a proxy, which is permitted, as discussed above, as long as it is supported by adequate evidence.[68] However, there is no evidence supporting that approach as the groundwater elevation minimum threshold suffers the flaws discussed above, and evidence in the draft GSP relating groundwater elevations to groundwater storage shows groundwater storage at historic lows by a wide margin when groundwater levels were 5 feet above the groundwater elevation minimum threshold in 2016.[69] Similarly, the draft Forebay Subbasin GSP sets the minimum threshold for groundwater storage based upon the groundwater elevation minimum threshold: "The minimum threshold groundwater elevation contours . . . were used to estimate the amount of groundwater in storage when groundwater elevations are held at the minimum threshold levels."[70] Again, there is no evidence supporting that approach as the groundwater elevation minimum threshold is flawed as discussed above, and evidence in the draft GSP shows the groundwater elevation minimum threshold results in historic lows in groundwater storage.[71] In fact, the groundwater elevation minimum thresholds allow for additional production in the subbasins over historic and current amounts so long as the subbasins do not experience another significant drought. There is no commitment in the draft GSPs that the production in the subbasins will be restricted to the estimated sustainable yield in the subbasins, and there is no model simulation showing the minimum threshold for groundwater elevations will prevent continued decline in groundwater storage.

Finally, the draft GSPs also utilize groundwater elevations as proxies to set the minimum thresholds for depletion of interconnected surface water.[72] But again, there is no evidence supporting this approach. These groundwater elevation proxies are at or near historic lows, and there is no evidence proving these elevations will prevent the depletion of interconnected surface water that would have a significant and unreasonable impact on beneficial uses. Rather, the draft GSPs merely state that these levels will not impact beneficial uses because there is not currently any litigation over surface water uses, and due to the operation of the Nacimiento Reservoir.[73] However, this statement does not acknowledge that decreased groundwater

elevations will increase depletion of the Salinas River, and reduce flow to downstream uses, including those uses in adjacent subbasins.[74] Lastly, the draft GSPs do not analyze how these minimum thresholds for depletion of interconnected surface water will impact adjacent subbasins.

In sum, the draft Forebay and Upper Valley GSPs require additional data and analysis to satisfy SGMA. These issues must be addressed before the GSPs are adopted, or the draft GSPs must be provide for their provision by a date certain.[75]

3. The Inadequacies in the Draft GSPs Addressed Above Threaten to Impinge Upon Water Rights

As stated previously, each of the groundwater sustainability agencies has an obligation to consider the interests of all beneficial users of the Basin[76] when implementing SGMA. Moreover, SGMA does not "determine[] or alter[] surface water rights or groundwater rights under common law or any provision of law that determines or grants surface water rights."[77]

By not analyzing potential impacts to adjacent subbasins in each draft GSP, the groundwater sustainability agencies disproportionately allocate the burden of sustainability across the Basin and threaten to impair groundwater users' rights in and to the Basin. This approach violates SGMA and must be addressed before the groundwater sustainability agencies adopt the draft GSPs or, as discussed above, through a commitment in the draft GSPs to modify or update their contents within a time certain.

III. THE DRAFT GSPS MUST INCORPORATE PROJECTS AND MANAGEMENT ACTIONS TO ACHIEVE SUSTAINABILITY

The GSP Regulations require each GSP to "include a description of the projects and management actions the Agency has determined will achieve the sustainability goal for the basin, including projects and management actions to respond to changing conditions in the basin."[78] Because the draft GSPs are lacking the data and analysis described in Section II above, the draft GSPs cannot meet this requirement (e.g., the draft GSPs' lack of analysis of impacts to adjacent basins prevents an adequate proposal of projects and management actions to achieve sustainability). Further, without understanding impacts on interbasin surface and subsurface flow and how implementation of the draft GSPs will impact adjacent subbasins, the groundwater sustainability agencies will be unable to properly assess the benefits associated with any future projects or management actions—e.g., if they propose projects involving dam operations, how can the groundwater sustainability agencies assess the benefits of those projects to the Lower Valley? Accordingly,

[74] aquilogic Memo, pp. 3-8, attached hereto as **Exhibit A**; DWR Water Budget BMP, pp. 4-5.

[78] GSP Regs., § 354.44(a).

the *Alliance* reserves the right to comment on the draft GSPs' proposed projects and management actions once the issues described above have been addressed.

However, as a preliminary note, the draft GSPs as currently presented do not include sufficient projects or management actions to achieve sustainable groundwater management Basin-wide. Rather, the draft GSPs appear to foist the burden of sustainable groundwater management on the Eastside, Langley, 180/400-Foot Aquifer, and Monterey Subbasins, while avoiding consequential projects and management actions in the Forebay and Upper Valley Subbasins. Indeed, the draft GSPs for the Eastside, Langley, and Monterey Subbasins each include a management action for pumping allocations and controls, but no such management action is included in the draft Forebay Subbasin or Upper Valley Subbasin GSPs.[79] Instead, the draft Forebay Subbasin and Upper Valley Subbasin GSPs include management actions that only superficially impact the subbasins—e.g., the proposed Subbasin "Sustainable Management Criteria Technical Advisory Committees," which require the formation of a "TAC for each Subbasin" that will "develop recommendations to correct negative trends in groundwater conditions and continue to meet the measurable objectives."[80] This issue must be addressed in the next draft of the GSPs.

The *Alliance* also notes that the draft GSPs do not mention the project proposed in the Hydrogeology and Water Supply of Salinas Valley White Paper prepared by the Salinas Valley Groundwater Basin Hydrology Conference for MCWRA in 1995 ("Salinas Valley White Paper"), which is attached hereto as **Exhibit E**. The "Conference" was a "panel of 10 geologists, hydrogeologists, and engineers familiar with Salinas Valley ground water basin" that was convened to "reach agreement on the basic physical characteristics of the basin, and the surface and ground water flow within the basin."[81] The Conference had a "remarkable unanimity of opinion" on the understanding of the "physical characteristics of the basin, the hydrologic system, the interaction between surface water and ground water, and definition of the specific ground water problems in the basin."[82] The Conference agreed that this understanding pointed "compellingly toward an already identified *regional* solution to the Valley's groundwater water resources problem" and recommended pursuing that solution.[83]

> The need for conjunctive operation of surface water and ground water storage was recognized as early as 1946. In 1946, the California Department of Water Resources published a report on Salinas Valley that described the occurrence of seawater intrusion and declining ground water levels. The report recommended a project to eliminate these problems that included development of surface water and ground water storage. Surface water storage was to be accomplished by the construction of dams on tributaries to Salinas River, and ground water storage was to be accomplished by ground water transfers from the Forebay Area to the Pressure Area and East [S]ide Area. The Department

[79] See Draft Eastside Subbasin GSP, § 9.4.12; Draft Langley Subbasin GSP, § 9.4.5; Draft Monterey Subbasin GSP, § 9.4.8; see also 180/400-Foot Aquifer Subbasin GSP, § 9.2 [water charges framework].
[80] Draft Upper Valley Subbasin GSP, § 9.4.1; Draft Forebay Subbasin GSP, § 9.4.1.
[81] *Id.* at p. 5.
[82] *Ibid.*
[83] *Ibid.*

> recommended transfer facilities that include wells in the Forebay Area, conveyance facilities from the Forebay Area to the Pressure and East Side Areas, and distribution facilities within the Pressure and East Side Areas. In such a conjunctive operation, the increased extraction in the Forebay Area and conveyance of water to the Pressure and East Side Areas would vacate ground water storage in the Forebay Area. This empty storage space would be refilled by additional infiltration from Salinas River . . . Part of the recommended facilities for surface water and ground water storage have been completed by the construction of the dams for San Antonio and Nacimiento reservoirs, but the facilities for the effective use of groundwater storage have not been completed. The operation of San Antonio and Nacimiento reservoirs has produced benefits to [S]alinas Valley, but the ultimate benefits that would result from the construction and operation of transfer facilities have not been realized. **The panel concluded that the facilities recommended in 1946 by the California Department of Water Resources should be completed immediately** . . . The result of partially completing the project has been an uneven distribution of benefits throughout the Valley. The Forebay Area and Upper Valley Areas have enjoyed relatively large benefits from San Antonio and Nacimiento reservoirs that would have been shared equally with the Pressure and East Side Areas if the intended transfer facilities had been built. In the absence of the transfer facilities, seawater intrusion into the Pressure Area and water-level declines within the East Side Area have not been mitigated.[84]

The Conference noted that this solution is practical as the "water resources problem in Salinas Valley is not a water supply problem. It is a water distribution problem. The basin has enough surface and ground water to meet existing and projected future average annual agricultural, and municipal and industrial water demand through the year 2030. The problem lies in managing those supplies to meet water demands at all locations in the Valley at all times."[85] This project is an example of integrated groundwater management for the Basin as a whole and should be included in the list of projects and management actions in each of the draft GSPs.[86]

IV. <u>CONCLUSION</u>

The *Alliance* appreciates the opportunity to provide these comments on the draft GSPs, as well as the groundwater sustainability agencies' consideration of the *Alliance*'s input. At present, the draft GSPs do not provide a sufficient basis for integrated management of the Basin given their inconsistent analytical approaches and inadequate analysis of impacts on adjacent subbasins. The *Alliance* makes these comments with the hope that these issues can be addressed through additional engagement prior to the adoption of the GSPs. It is critical that the groundwater sustainability agencies lay the foundation now for the integrated sustainable management of the Basin; without such a foundation, the agencies will not be able to satisfy their obligations under SGMA.

Subject: Comments on Draft Groundwater Sustainability Plans for the Eastside Aquifer, Forebay Aquifer, Upper Valley Aquifer, Langley Area, and Monterey Subbasins of the Salinas Valley Groundwater Basin

Project No.: 018-09

Aquilogic, Inc. (**aquilogic**) is pleased to provide this memorandum on behalf of the Salinas Basin Water Alliance (SBWA). The curricula vitae for Mr. Brown and Dr. Abrams are provided in **Attachment A**. The memorandum provides our comments on the following draft Groundwater Sustainability Plans (GSPs) prepared by the Salinas Valley Basin Groundwater Sustainability Agency (SVBGSA):

- Upper Valley Aquifer Subbasin (Upper Valley)
- Forebay Aquifer Subbasin (Forebay)
- Eastside Aquifer Subbasin (Eastside)
- Langley Area Subbasin (Langley), and
- Monterey Subbasin (Monterey)

The draft GSP for the Monterey was prepared jointly with the Marina Coast Water District (MCWD) GSA.

Aquilogic's analysis of the five draft GSPs found a significant deficiency with four of the five plans: The impact of the draft GSPs on adjacent subbasins is not sufficiently evaluated in the draft GSPs for the Upper Valley, Forebay, Eastside, and Langley. These impacts may hinder or prevent adjacent subbasins from achieving sustainability. The impacts on adjacent subbasins occur because all subbasins in the Salinas Valley Groundwater Basin (SVGB) are hydrologically and hydraulically connected. The impacts are caused by two factors: (1) unreasonably low minimum thresholds (MTs) for the chronic lowering of groundwater levels and (2) groundwater extractions that reduce flows to adjacent subbasins or reverse natural hydraulic gradients.

These two factors are linked because the unreasonably low MTs allow groundwater extractions to continue at or above their current magnitude.

The draft GSPs relied on the Salinas Valley Integrated Hydrologic Model (SVIHM) and the Salinas Valley Operational Model (SVOM) for much of their content. The SVIHM and the SVOM are not publicly available at this time. Thus, stakeholder review of the GSPs, especially the content that relies heavily on the models, is hampered by an inability to access, evaluate, and run these models. **Aquilogic** reserves the right to supplement our comments at a later date as the models, model data, assumptions, and results become available.

Connected Subbasins

It has long been recognized and accepted that the subbasins comprising the SVGB are hydraulically connected, with groundwater flowing between adjacent subbasins (Division of Water Resources [DWR], 1946; Salinas Valley Ground Water Basin Hydrology Conference [SVGWBHC], 1995; Monterey County Water Resources Agency [MCWRA], 2001; Kennedy/Jenks, 2004). For example, MCWRA (2001) states that the Salinas Valley hydrologic subareas, which are generally coincident with the six subbasins under the purview of the SVBGSA, are "*…hydrologically and hydraulically connected…*" and that "*[l]andowners and other water users pumping groundwater* [from the Valley] *are drawing water from the same groundwater basin*." In other words, what happens in one subbasin can affect the other subbasins. There are numerous sections within the GSPs (see **Attachment B**) that state "the GSP needs to consider potential for groundwater flow between these adjacent subbasins." However, the GSPs generally do not consider these flows in terms of impacts on adjacent subbasins, nor do the GSPs assess the impact on adjacent subbasins of reaching or exceeding the MTs and measurable objectives (MOs) in one or more subbasins.

Other statements in the GSPs regarding subbasin boundaries are incorrect or contradictory. For example, page 4-10 of the draft Eastside GSP states: "*The southeastern boundary* [of the Eastside] *with the adjacent Forebay Subbasin is near the town of Gonzales (DWR, 2004). It is extended from the approximate southern limit of the regional clay layers that are the defining characteristic of the southern extent of the 180/400-Foot Aquifer Subbasin. There may be reasonable hydraulic connectivity with the Forebay Subbasin, although the principal aquifers change from relatively unconfined to confined near this boundary*." The last sentence of this passage conflicts with the statement on page 4-18 of the draft Eastside GSP, where it is stated: "*In addition to the fact that aquifer material cannot be correlated between boreholes, no evidence exists for a discrete confining layer in the Subbasin (Brown and Caldwell, 2015)*."

Another example of a contradictory statement regarding subbasin boundaries occurs on page 4-10 of the draft Eastside GSP, as well as on page 4-9 of the 180/400 GSP, where it is stated: "*Previous studies of groundwater flow across this boundary* [i.e., between the Eastside and

180/400] *indicate that there is restricted hydraulic connectivity between the subbasins*." The references for these previous studies should be provided, because this statement is an apparent contradiction with other statements in the draft Eastside GSP (e.g., p. 4-21 of the draft GSP, "*Subsurface recharge is primarily from inflow from the adjacent Forebay and 180/400-Foot Aquifer Subbasins to the south and west, respectively (DWR, 2004)*." The apparent uncertainty regarding the nature of the boundary between the Eastside and 180/400 should be listed as an identified data gap on page 4-35 of the draft Eastside GSP.

A detailed list of additional statements from the GSPs that establish and describe the subbasin interconnections is provided as **Attachment B**.

Minimum Thresholds and Groundwater Extractions

As described below, the evidence presented in the draft GSPs indicates that groundwater extractions in the Upper Valley deplete inter-subbasin groundwater flows to the Forebay. Groundwater extractions in the Forebay deplete inter-subbasin groundwater flows to the 180/400 and Eastside and streamflow to the 180/400. Groundwater extractions in the Eastside and Langley reduce groundwater levels in those subbasins to the point where they cause, or have the potential to cause, groundwater flow from the 180/400 to the Eastside and Langley, which is the reverse of the natural groundwater flow direction (i.e., the natural flow direction is from higher topographic elevation to lower topographic elevation). These conditions are likely exacerbating seawater intrusion (SWI) in the 180/400 and hinder or may even prevent that subbasin from achieving sustainability. Additionally, extractions in the 180/400, combined with inter-subbasin flow from the 180/400 to the Eastside, and potentially from the 180/400 to the Langley, has lowered groundwater levels to the point where groundwater is induced to flow from the Monterey to the 180/400.

These conditions are likely to persist indefinitely because the draft GSPs set unreasonably low MTs for the chronic lowering of groundwater levels, and projects and management actions, in general, appear to be insufficient to overcome these problems. Moreover, the unreasonably low MTs facilitate groundwater extractions at current or increased rates in the Upper Valley, Forebay, Eastside, and potentially the Langley, despite the issues described in the previous paragraph.

MTs and MOs have been set to differing levels in adjacent basins. The GSPs do not explain why such differences are appropriate and why or how they would lead to achieving sustainability throughout the SVGB. **Aquilogic** finds no significant analysis or discussion in the draft GSPs for the Upper Valley, Forebay, Eastside, or Langley on the impact of differing MTs and MOs or on the potential impacts of alternative MTs and MOs.

Upper Valley

The draft GSP for the Upper Valley states that locally defined significant and unreasonable groundwater elevations in the subbasin include groundwater levels that "*[a]re at or below the observed groundwater elevations during the 2012 to 2016 drought*."[1] However, the MT for the chronic lowering of groundwater levels is set five feet *lower* than the lowest level recorded between the drought years of 2012 and 2016.[2] In terms of the cumulative change in average groundwater levels, the MT is five feet *lower* than the 2016 level, which was the lowest average groundwater level ever recorded.[3] The 2016 level has never been exceeded since record keeping began in 1944, and that level occurred only because of the 2012-2016 drought. The next lowest level occurred in 1990, also during a severe drought, and was 8.5 feet higher than the 2016 level.[3] Nevertheless, groundwater levels have in general been stable over time in the Upper Valley due to the operation of Nacimiento and San Antonio reservoirs (SVGWBHC, 1995).[3]

Aquilogic finds that the history of groundwater levels in the Upper Valley[3] indicates the MT for chronic lowering of groundwater levels will only be exceeded if: (1) there is an unprecedented increase in groundwater extractions, and/or (2) an unprecedented, severe drought occurs. Importantly, the very low MT for groundwater levels facilitates increased groundwater extractions in the Upper Valley (perhaps significantly increased extractions), without triggering the "undesirable result" defined in the draft GSP.[4] By setting the MT for chronic lowering of groundwater levels at five feet lower than the historic low, undesirable results may occur. Further, the potential impact of increased pumping in the Upper Valley is ignored. Increased pumping could lower groundwater levels down to the MT, which would have impacts on the remainder of the SVGB.

SVBGSA acknowledges that groundwater extractions estimated by the SVIHM are only 76% of reported extractions in the Upper Valley.[5] The extractions estimated for the historical water budget were consequently updated to reflect this discrepancy, but the other groundwater budget components, some of which are linked to groundwater extractions, were not updated, although they should have been prior to completing the draft GSP.[6] Because of this, the following discussion relies on the SVIHM-calculated groundwater-budget components, for comparison purposes. It should be noted that the impacts described below could be determined to be even more significant, if and when pumping in the model is fixed.

---

[1] Page 8-7 of the draft Upper Valley GSP.
[2] Table 8-1, page 8-6 of the draft Upper Valley GSP
[3] Figure 8-2, page 8-12 of the draft Upper Valley GSP
[4] Increased extractions might be limited by the MT for depletion of interconnected surface water (ISW), which is set to 2016 groundwater levels in shallow wells near ISW. However, it follows that 2016 shallow-well groundwater levels are also likely to be the lowest levels in recorded history.
[5] Page 6-17 of the draft Upper Valley GSP
[6] Our understanding is that the USGS is working on resolving SVIHM issues such as these.

Prior to construction of Nacimiento and San Antonio reservoirs, groundwater levels in the Upper Valley were declining substantially.[7] In response to conservation releases from these two reservoirs, which flow to the Salinas River, groundwater levels in the Upper Valley began recovering in 1957 and have since stabilized. During the draft GSP's historical period (i.e., 1980-2016, post operation of the reservoirs), groundwater extractions (-91,600 acre-feet per year [AFY]) in the Upper Valley were supported by net stream exchange (89,100 AFY).[8]

On average, the draft GSP states that pumping in the Upper Valley does not substantially increase stream depletion. Although the draft GSP concludes that only an average of 1,100 AFY of stream depletion is caused by pumping (mostly limited to the Salinas River),[9,10] it should be noted that **aquilogic** believes the depletion value may be higher, because the method employed by SVBGSA to estimate stream depletion with the SVIHM does not account for stream cells that are connected to groundwater for less than 50% of the model period and, as noted above, the SVIHM underestimates pumping by 24%. It is expected that stream cells connected to groundwater for less than 50% of the model period (e.g., 48%) would also contribute to stream depletion. Furthermore, limiting the stream-depletion discussion in the draft GSP to the historical average obscures the higher stream depletions that would occur during drought years. Without understanding drought year depletion, the impact on adjacent basins during droughts cannot be assessed. Despite these limitations in the model results, **aquilogic** opines that *decreases* in current groundwater extractions in the Upper Valley would result in proportional *increases* in subsurface flow from the Upper Valley to the Forebay, as illustrated by the following discussion.[11]

The draft GSP's estimated stream depletion (due to pumping) is only 1% of the net stream exchange, which implies that streamflow infiltration along the Salinas River in the Upper Valley would be of the same order with or without pumping. The infiltration occurs due to the relatively high streambed conductivity and hydraulic conductivity of the surrounding aquifer, in conjunction with a hydraulic gradient that is directed away from the streambed and into the Upper Valley aquifer. Because of these conditions, and the fact that 99% of the net stream exchange occurs without the influence of groundwater extractions, **aquilogic** finds that the absence of pumping would not result in significant groundwater discharge into the Salinas River in the Upper Valley. Therefore, on average, Upper Valley pumping captures groundwater that would otherwise flow to the adjacent Forebay. On average, for the historical period, the Forebay receives only 7,700 AFY of subsurface flow from the Upper Valley.[12] This amount would

---

[7] Figure 5-8, page 5-13 of the draft Upper Valley GSP
[8] Table 6-10, page 6-22 of the draft Upper Valley GSP
[9] Table 5-4, page 5-31 of the draft Upper Valley GSP
[10] Figure 4-11, page 4-26 of the draft Upper Valley GSP
[11] The SBWA has previously asked the SVBGSA to conduct simulations with the SVIHM that would address this issue (see Attachment C).
[12] Table 6-6, p. 6-17 of the draft Forebay GSP

be higher if groundwater extractions in the Upper Valley were lower, which constitutes an impact on the adjacent Forebay. This impact cascades through the Forebay and into the 180/400 and the Eastside, and potentially the Monterey, and should be analyzed in the draft GSP.[11]

It should not be ignored that if groundwater extractions were to increase enough in the Upper Valley (relative to the historical average), groundwater levels could be lowered to the point where they are at or near the MT for the chronic lowering of groundwater levels (and the MT for depletion of ISW), which would result in substantially more stream depletion due to pumping than is revealed by limiting the analysis to historical averages. The draft Upper Valley GSP does not, but should, analyze this.

In summary, the draft Upper Valley GSP does not consider the undesirable results that would occur if the MTs were reached or exceeded, both within the Upper Valley and within downstream subbasins. This issue should be addressed before the Upper Valley GSP is finalized.

Forebay

In the draft GSP for the Forebay, the MT for the chronic lowering of groundwater levels is set to 2015 levels.[13] In terms of the cumulative change in average groundwater levels, this is the second lowest level on record.[14] The 2015 level has been exceeded once in recorded history, in 2016, when the average groundwater level was four feet lower. These low levels occurred only due to the 2012-2016 drought. The next lowest level occurred in 1991, also during a severe drought, and was 14.5 feet higher than the 2016 level.[14] Nevertheless, average groundwater levels have generally been stable over time in the Forebay due to the operation of Nacimiento and San Antonio reservoirs (SVGWBHC, 1995).[14]

Aquilogic finds that the history of groundwater levels in the Forebay[14] indicates the MT for chronic lowering of groundwater levels will only be exceed if: (1) there is an unprecedented increase in groundwater extractions, and/or (2) a severe drought occurs. Importantly, the very low MT for groundwater levels facilitates increased groundwater extractions in the Forebay under average conditions (perhaps significantly increased extractions), without triggering the "undesirable result" defined in the draft GSP.[15] By setting the MTs at 2015 levels, four feet above the historic low, undesirable results may occur. Further, the potential impact of increased pumping in the Forebay is ignored. Increased pumping could lower groundwater levels down to the MT, which would have impacts on the remainder of the SVGB.

[13] Table 8-1, page 8-6 of the draft Forebay GSP
[14] Figure 8-2, page 8-14 of the draft Forebay GSP
[15] Increased extractions might be limited by the MT for depletion of ISW. The MT for depletion of ISW is set by proxy to 2015 groundwater levels, for shallow groundwater near locations of ISW, which are also likely at or near historic lows.

SVBGSA acknowledges that groundwater extractions estimated by the SVIHM are only 65% of reported extractions in the Forebay.[16] The extractions estimated for the historical water budget were consequently updated to reflect this discrepancy, but the other groundwater budget components, some of which are linked to groundwater extractions, were not updated, although they should have been prior to completing the draft GSP. Because of this, the following discussion relies on the SVIHM-calculated groundwater-budget components, for comparison purposes. It should be noted that the impacts described below could be determined to be even more significant, if and when pumping in the model is fixed.

Prior to construction of Nacimiento and San Antonio reservoirs, groundwater levels in the Forebay were declining substantially.[17] In response to conservation releases from these two reservoirs, which flow to the Salinas River, groundwater levels in the Forebay began recovering in 1957 and have since stabilized. During the draft GSP's historical period (i.e., 1980-2016, post operation of the reservoirs), groundwater extractions (-108,700 AFY) in the Forebay were supported by net stream exchange (90,300 AFY).[18]

On average, pumping in the Forebay substantially increases stream depletion. According to the draft Forebay GSP, an average of 29,700 AFY of stream depletion along the Salinas River is caused by Forebay pumping.[19] It should be noted that **aquilogic** believes the depletion value may be higher, because the method employed by SVBGSA to estimate stream depletion with the SVIHM does not account for stream cells that are connected to groundwater for less than 50% of the model period, and as noted above, the SVIHM underestimates pumping by 35%. It is expected that stream cells connected to groundwater less than 50% of the model period (e.g., 48%) would also contribute to stream depletion. Furthermore, limiting the stream depletion discussion in the draft GSP to the historical average obscures the higher stream depletions that would occur during drought years. Without understanding drought year depletion, the impact on adjacent basins during droughts cannot be assessed. Despite these limitations in the model results, **aquilogic** opines that *decreases* in groundwater extractions in the Forebay would cause *increases* in subsurface flow from the Forebay to the Eastside and 180/400 and *increases* in surface flow from the Forebay to the 180/400, as illustrated by the following discussion.[11]

The reported stream depletion (due to pumping) value is 33% of the net stream exchange, which implies that substantial streamflow is captured by groundwater pumping in the Forebay. The draft Forebay GSP states that 31% of the stream depletion along the Salinas River occurs during the principal conservation period for reservoir releases,[19] and therefore is a desired outcome.[20] However, the draft GSP should also acknowledge that streamflow not depleted in

---

[16] Page 6-19 of the draft Forebay GSP
[17] Figure 5-7, page 5-11 of the draft Forebay GSP
[18] Table 6-12, page 6-23 of the draft Forebay GSP
[19] Table 5-4, page 5-30 of the draft Forebay GSP
[20] Page 8-42 of the draft Forebay GSP

the Forebay would flow to the 180/400, where streamflow infiltration of reservoir releases is also a desired outcome. **Aquilogic** finds that it is possible, but unlikely, that the absence of pumping would result in significant groundwater discharge into the Salinas River in the Forebay. Therefore, on average, Forebay pumping captures groundwater that would otherwise flow to the adjacent 180/400 and Eastside and captures streamflow that would otherwise flow to the 180/400. These inter-subbasin flows would be higher if Forebay pumping were lower, which constitutes an impact on the adjacent 180/400 and Eastside. The proportion of unpumped groundwater that would become subsurface flow to adjacent subbasins, relative to surface flow to the adjacent 180/400, is currently unknown but could be estimated with the SVIHM. The SBWA has repeatedly asked the SVBGSA to conduct simulations that would address this issue (see **Attachment C**). Regardless, the impacts on adjacent subbasins should be analyzed in the draft GSP.

It should not be ignored that if groundwater extractions were to increase enough in the Forebay (relative to the historical average), groundwater levels could be lowered to the point where they are at or near the MT for the chronic lowering of groundwater levels (and the MT for depletion of ISW), which would result in substantially more stream depletion due to pumping than is revealed by limiting the analysis to historical averages. The draft Forebay GSP does not, but should, analyze this.

In summary, the draft Forebay GSP does not consider the undesirable results that would occur within downstream subbasins if the MTs were reached or exceeded. This issue should be addressed before the Forebay GSP is finalized.

Eastside

In the draft GSP for the Eastside, the MT for the chronic lowering of groundwater levels is set to 2015 levels.[21] In terms of the cumulative change in average groundwater levels, this level has only been exceeded during the drought years of 1990-1993 and 2016.[22] That is, these low levels occurred only due to severe droughts. The MTs for reductions in groundwater storage and depletion of ISW in the Eastside are also set to 2015 groundwater levels, by proxy.[21,23]

Declining groundwater storage is documented in the Eastside,[24,25] although the magnitude is uncertain. The average storage decline initially estimated in the draft Eastside GSP is 3,400 AFY

[21] Table 8-1, page 8-6 of the draft Eastside GSP
[22] Figure 8-3, page 8-13 of the draft Eastside GSP
[23] However, the SVIHM-simulated cumulative change in storage does not correlate well with the average change in groundwater elevation (Figure 8-6, page 8-25 of the draft Eastside GSP). This is particularly true for the 1991-1998 period, during which groundwater levels were increasing, but the model shows ongoing storage declines.
[24] Figure 5-14, page 5-21 of the draft Eastside GSP
[25] Figure 6-10, page 6-21 of the draft Eastside GSP

for the years 1944-2019, based on groundwater elevation changes and an assumed storage coefficient.[26] Brown and Caldwell (2015) reported an average decline in groundwater storage in the Eastside of 5,000 AFY between 1944 and 2013.[27] On the other hand, the SVIHM calculates an average groundwater storage decline of 21,700 AFY from 1980 to 2016.[28] The draft Eastside GSP states that the SVIHM storage-decline estimate is "…*more consistent with drought year estimates than the long-term historical average estimates*," because it is similar in magnitude to the 25,000 AFY to 35,000 AFY storage decline estimated by Brown and Caldwell (2015) for the drought years of 1984-1991.[27] Because of these uncertainties, the draft Eastside GSP adopts an average of available estimates and states that the historical loss of groundwater storage is 10,000 AFY.[29] However, SVBGSA acknowledges that SVIHM-estimated groundwater pumping in the Eastside is only 81% of reported extractions,[30] which **aquilogic** interprets to mean that the SVIHM estimate of storage decline is also likely underestimated. Improving the estimated change in groundwater storage should be a priority for the SVBGSA, so that potential future changes in storage can be more readily assessed.

As noted, the draft Eastside GSP indicates that "undesirable results" for the chronic lowering of groundwater levels can be avoided in the Eastside by maintaining average groundwater levels at or above 2015 levels. Despite not triggering an "undesirable result,", **aquilogic** finds that groundwater elevation maps for 2015 show persistent and widespread groundwater flow from the 180/400 to Eastside in the Salinas area (i.e., southwest to northeast, at and near the subbasin boundary).[31,32] Importantly, the natural groundwater flow direction in this area is northeast to southwest (i.e., from higher topographic elevation to lower topographic elevation). The 2015 groundwater elevations show a reversal of the natural flow direction which, as stated, induces groundwater flow from the 180/400 to the Eastside. This flow direction is likely exacerbating SWI in the 180/400 and will likely continue to do so into the future. By setting the MTs at 2015 levels, which are near historic lows, undesirable results may occur. Further, the potential impact of increased pumping in the Eastside is ignored. Increased pumping could lower groundwater levels down to the MT, which would have impacts on the remainder of the SVGB.

Because the MTs for chronic lowering of groundwater levels, reduction of groundwater storage, and depletion of ISW are set to 2015 groundwater levels, **aquilogic** finds that sustainability, in terms of these three sustainability indicators (SIs), may come at the expense of the 180/400's ability to achieve sustainability for its SIs, particularly for SWI. The MT for SWI in the 180/400 is

[26] Pages 5-19 to 5-20 of the draft Eastside GSP
[27] Page 6-22 of the draft Eastside GSP
[28] Table 6-10, page 6-22 of the draft Eastside GSP
[29] Page 6-23 of the draft Eastside GSP
[30] Page 6-17 of the draft Eastside GSP
[31] https://www.co.monterey.ca.us/home/showpublisheddocument/31286/636355521174600000
[32] https://www.co.monterey.ca.us/home/showpublisheddocument/31284/636355520821470000

the 2017 extent of the 500 mg/L chloride isocontour.[33] This MT has already been exceeded,[34] which constitutes an undesirable result.[33] If average groundwater levels in the Eastside persist at the MT (i.e., 2015 groundwater levels), it may not be possible for the 180/400 to avoid undesirable results in terms of SWI. Note that the most promising project in the 180/400 for limiting SWI, a proposed SWI extraction barrier, will not address existing inland SWI.[35] Furthermore, the MT for SWI in the Eastside is the 500 mg/L chloride isocontour at the Subbasin boundary which, based on the current locations of that isocontour in the 180-Foot Aquifer and the 400-Foot Aquifer,[34] will not discourage Eastside pumping for many years, a scenario that may prevent the 180/400 from achieving sustainability.

Aquilogic finds that the measurable objective (MO) for chronic lowering of groundwater levels in the Eastside, which is set to 1999 groundwater levels, also allows continued groundwater flow from the 180/400 to the Eastside.[36] The sole groundwater contour map prepared for 1999 by the MCWRA shows that, similar to 2015, there was also persistent and widespread groundwater flow from the 180/400 to the Eastside,[37] as do maps from other sources,[38] particularly in and around the City of Salinas. Such southwest-to-northeast groundwater flow in 1999, which as noted is the reverse of the natural groundwater flow direction, likely exacerbated seawater intrusion in the 180/400, and would likely continue to do so even if the MOs for the chronic lowering of groundwater levels in the Eastside are achieved. To illustrate, there were substantial increases in SWI between 1997 and 1999, and between 1999 and 2001, in both the 180-Foot Aquifer[39] and the 400-Foot Aquifer.[40] Pumping in the 180/400 plays a role in ongoing SWI in the 180/400; however, northeastward groundwater flow to the Eastside in and around Salinas also plays a role. It should be noted that these increases in SWI in the 180/400 occurred during a time when groundwater levels were *increasing* in the Eastside (i.e., 1995-1999).[22] These issues—the potential for the Eastside MTs and MOs to exacerbate SWI in the 180/400—should be addressed in the draft GSP before the SVBGSA considers the document for adoption.

Aquilogic opines that, under the MTs set by the draft GSP, groundwater extractions in the Eastside could likely continue at their current magnitude, or perhaps even at a greater magnitude, despite the ongoing concerns described above. This opinion is supported by recent data. The draft Eastside GSP states that, "*[a]n undesirable result for chronic lowering of groundwater levels does not currently exist*…"[41] due to all representative monitoring sites being

---

[41] Page 8-22 of the draft Eastside GSP

above their MTs in 2019. Because two other SIs use groundwater levels as proxies,[21] and due to other conditions related to the remaining SIs, the Eastside is currently sustainable, despite a history of chronic loss of groundwater storage and reversed groundwater flow that threatens to make sustainability in the 180/400 unachievable. It appears that the draft GSP could facilitate increased pumping, further impacting the 180/400, as groundwater contour maps for 2019 show the same persistent reversed groundwater flow from the 180/400 to the Eastside in and around Salinas that was observed in 1999 and 2015.[42] As previously noted, the draft Eastside GSP ignores the potential impact that increased pumping in the Eastside, which could lower groundwater levels down to the MT, may have on the remainder of the SVGB.

In summary, the Eastside GSP does not consider the undesirable results that would occur if the MTs and MOs were reached or exceeded, both within the Eastside and within the 180/400. This issue should be addressed before the Eastside GSP is finalized.

Langley

The MT for the chronic lowering of groundwater levels in the Langley is difficult to evaluate in a historical context, due to a lack of data. It is set at 2019 groundwater levels,[43] but in terms of the cumulative change in average groundwater levels,[44] there are no values for 2015 or for the drought years 1989-1991. The 2019 levels are among the lowest on record, and the lowest levels since 1994, but values on the order of 1-2 feet lower have been recorded.

Simulations with the SVIHM indicate net subsurface flow out of the Langley to the 180/400.[45] However, **aquilogic** finds that groundwater in the southwestern portion of the Langley flows from the 180/400 to the Langley,[46] which risks exacerbating SWI in the 180/400 and possibly preventing 180/400 from achieving sustainability in terms of SWI. Furthermore, the SWI MO and MT for the Langley state that the 500 mg/L chloride isocontour must not cross the Langley boundary from the 180/400.[43] If the 500 mg/L isocontour were to approach or cross the subbasin boundary, the SWI MT in the 180/400 would have been exceeded long before SWI MT in the Langley would be exceeded, a scenario that may prevent the 180/400 from achieving sustainability and could facilitate increased pumping in the Langley. Again, these issues should be analyzed before the GSP is finalized.

Monterey

The MT for the chronic lowering of groundwater levels in the Monterey is also difficult to evaluate, in part because changes to MTs and MOs occurred after the draft GSP was issued and

[43] Table 8-1, page 8-6 of the draft Langley GSP
[44] Figure 8-2 of the draft Langley GSP
[45] Table 6-8, page 6-19 of the draft Langley GSP
[46] Figure 5-11, page 5-20 of the draft Langley GSP

the matter is still unresolved. In the Marina-Ord management area, the MT is set to the lowest groundwater level between 1995 and 2015.[47] It is our understanding that this MT will not change. In the Corral de Tierra management area, the draft GSP states that the MT for the chronic lowering of groundwater levels is set to 2015 groundwater levels.[47] However, it is our understanding, gleaned from public meetings, that that this level was changed to 2008 levels at a recent subbasin meeting and that the matter will be discussed in an upcoming subbasin meeting.

Descriptions of the Deep Aquifers in the draft Monterey GSP suggest that "*[t]here is a strong likelihood of flow through these confining layers (MCWRA, 2018).*"[48] **Aquilogic** believes this statement is speculative and not supported by water quality data. A detailed study of the Deep Aquifers by the SVBGSA will commence in the near future, which will likely provide additional insight into the nature of the confining layers in the Deep Aquifers. Until that study is completed, the draft GSP should avoid speculation.

The draft GSP for the Monterey used the Monterey Subbasin Groundwater Flow Model (MBGWFM) to determine historical, current, and projected water budgets, rather than the SVIHM. Under historical groundwater conditions, there is a net flow of groundwater out of the Monterey and into the 180/400.[49] For the projected water budget, multiple simulations were conducted with the MBGWFM to assess, among other things, the impact of possible future conditions in the 180/400. Under all reasonably foreseeable groundwater conditions in the 180/400, groundwater outflow from Monterey to 180/400 continues to occur.[50] These conditions could hinder or prevent the Monterey from achieving sustainability, and the draft GSP should address this more thoroughly.

Projects and Management Actions

Potential projects and management actions are listed and described in each of the draft GSPs and the 180/400 GSP for the SVGB in Monterey County. While lengthy, the list is not exhaustive. Furthermore, there has not been a comprehensive effort to simulate project benefits with the available models; thus, the potential effectiveness of many of the proposed projects and management actions is unknown.

Missing from the analysis of potential projects is perhaps the one project that could balance all or most of the water demands in the Monterey County portion of the SVGB. That project is the surface conveyance of groundwater extracted from the Forebay to be delivered to the Eastside and 180/400. This project was first proposed in DWR Bulletin 52 in 1946 as the second

[47] Table 8-1, page 8-11 of the draft Monterey GSP
[48] Page 36 of Chapter 4 of the draft Monterey GSP
[49] Table 6-1, page 6-20 of the draft Monterey GSP
[50] Table 6-4, page 6-44 of the draft Monterey GSP.

component of a larger project that included impoundment of surface water to provide conservation releases to the Salinas River. The surface impoundments were built: Nacimiento and San Antonio reservoirs. The groundwater extraction facilities and surface conveyance were never constructed. SVGWBHC (1995) found the 1946 solution, "…*so compelling we could not refrain from recommending it*." SVGWBHC (1995) also stated that, "*More recent studies conducted by MCWRA since 1946 have reaffirmed and endorsed the original concepts*." In addition, SVGWBHC stated:[51]

> "*We urge the MCWRA to focus its attention on the completion of the original plan by the construction and operation of water transfer facilities. The MCWRA should avoid diverting its attention to suggested alternatives that are less viable economically or less effective technically. These less viable and less effective alternatives would not provide the same benefits as the original plan, would be more expensive, and the projected price of water would be significantly higher for all parties.*
>
> *The panel believes strongly that Salinas Valley is fortunate that an in-Valley solution is available. We urge the Salinas Valley community to support the MCWRA in this effort to distribute the available water supplies for more efficient water management and lasting benefits for all residents of the Valley*."

In the era of the Sustainable Groundwater Management Act (SGMA), one need only replace "MCWRA" with "SVBGSA" in the above quote.

Delivery of Forebay groundwater extractions from such a project to the 180/400 for SWI mitigation and to the Eastside for overdraft mitigation has the potential to restore the natural groundwater flow direction in the Eastside by providing in-lieu recharge. Significantly, delivery of this water to the 180/400 may have the potential to restore SWI protective elevations, as described in Geoscience (2013), also via in-lieu recharge, and may also be able to provide water to a SWI injection barrier in the 180/400.

Aquilogic strongly encourages the SVBGSA to consider including this project in all of the GSPs.

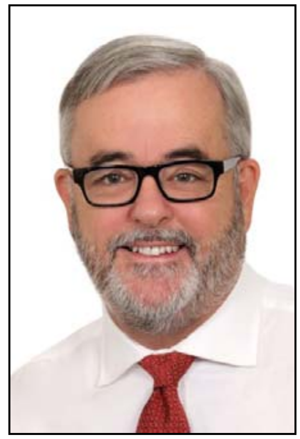
CURRICULUM VITAE

September 2021



Anthony Brown

Principal Hydrologist

mobile: +1.949.939.7160
email: anthony.brown@aquilogic.com

Disciplines

Hydrology, Hydrogeology, Water Resources, Water Quality, Water Supply, Drinking Water Treatment, Contaminant Source Identification, Contaminant Fate and Transport, Soil and Groundwater Remediation, Environmental Liability Management, Legal and Regulatory Strategy.

Education

M.Sc. Engineering Hydrology, Imperial College London, 1989
D.I.C. Postgraduate diploma in Civil Engineering, Imperial College London, 1988
B.A. Geography, King's College London, 1985

Professional Experience

Anthony is a versatile and proficient professional with over 30 years of experience in hydrology, hydrogeology, water resources, water quality, fate and transport of contaminants, groundwater remediation, regulatory strategy, water resources evaluation, and water supply engineering.

Anthony has conducted and managed numerous groundwater resources projects, including:

- resource evaluation, development and management
- water balance, storage capacity and safe yield analysis
- water rights disputes and adjudication
- marginal groundwater development (e.g., brackish water)
- aquifer storage and recovery (ASR)
- indirect potable reuse (IPR).

He has also implemented hundreds of hazardous waste site investigations, including sites with multiple potentially responsible parties (PRPs), complex hydrogeology and fate and transport, fractured rock, multiple contaminants, and co-mingled plumes. This work has included detailed Remedial Investigation (RI) or Phase II characterization studies, groundwater flow and solute transport modeling, Preliminary Endangerment Assessments, Human Health Risk Assessments, and remedial feasibility studies (FS), remedial system design and implementation. Anthony has been involved in the design, testing, and permitting of drinking water treatment systems for impaired (contaminated) water sources.

Anthony has provided expert services to many prominent water and environmental law firms, the Attorneys General of California, New Jersey, Pennsylvania, Maryland, Ohio, North Carolina, and Puerto Rico, several County District Attorneys, and numerous City Attorneys' Offices.

Through his work for water utilities impacted by gasoline constituents (e.g. MTBE), chlorinated solvents (e.g. PCE, TCE), solvent stabilizers (e.g. 1,4-dioxane), soil fumigants (e.g. 1,2,3-TCP), chlorofluorocarbons (e.g. Freon 11, 12 and 113), perfluorinated compounds (i.e., PFAS), the rocket propellants perchlorate and NDMA, and hexavalent chromium, arsenic and other metals, Anthony has become a recognized expert in the fate, transport, and remediation of these compounds, and the protection of source waters from contamination by such recalcitrant chemicals.

Amongst other technical areas of expertise, he has also provided expert advice related to:
- groundwater resource development
- groundwater basin management
- California Sustainable Groundwater Management Act (SGMA)
- water rights and the development of physical solutions
- groundwater discharges and the Clean Water Act
- compliance with the Comprehensive Environmental Response Compensation and Liability Act (CERCLA) and National Contingency Plan (NCP)
- cleanup under the Resource Conservation and Recovery Act (RCRA)
- the environmental impact of oil field contaminants and their mitigation
- source identification and mitigation of bacteria and fecal contamination in coastal waters
- source identification and persistence of microplastics in coastal waters.

Through his extensive experience on "high-profile" projects, Anthony has developed an excellent working relationship with private and public sector clients, Federal, State, and local elected officials and government agency staff, the legal community, professional organizations, non-profit environmental organizations, and his colleagues in the environmental and water resources professions.

Anthony has also testified before the U.S. Senate and briefed White House staff, federal, State, and local elected officials and regulators, independent commissions, professional groups, academic institutions, and the news media (including CBS 60 Minutes, National Public Radio [NPR] and local newspapers) on groundwater issues.

Beyond his US experience, Anthony has worked on projects in the United Kingdom, Ireland, Canada, Mexico, Costa Rica, Columbia, Ecuador, Yemen, Egypt, and Nepal.

U.S. Senate Testimony and Briefings for Elected Officials

- Testimony before the U.S. Senate Committee on Environment and Public Works on "the Appropriate Role of States and the Federal Government in Protecting Groundwater", on April 18, 2018.
- Briefing for White House Officials and the Council on Environmental Quality on "the Impact of MTBE on Water Resources of the United States", in October 1997.
- Briefing for U.S. Senators Feinstein and Boxer on "MTBE Contamination of the City of Santa Monica Water Supply", in October 1997.
- Briefing for Assistant Administrators and other leadership at the US Environmental Protection Agency (EPA) on "the Impact of MTBE on Water Resources of the United States", in October 1997.
- Briefing of State Senator Sheila Kuehl, several Assembly members, leadership at the California Environmental Protection Agency (CalEPA) and State Water Resources Control Board (SWRCB) on "MTBE Contamination of the City of Santa Monica Water Supply", in 1997-1998

Anthony has also briefed the following on the impact of fuel oxygenates, chlorinated solvents, rocket propellants, metals, oil field activities, and bacteria on water quality:

- USEPA staff (Region IX)
- State Senators and Assembly Members
- State regulators
- Local officials (Mayors, council and board members, City attorneys, etc.)
- Independent Commissions
- Professional bodies (ABA, ACS, ACWA, AEHS, AGWA, NGWA, GRA, etc.)
- Academic institutions and many other organizations
- Media outlets (NPR, CBS 60 Minutes, local TV stations)

Expert Consulting and Witness Services

Anthony is a respected, credible, and highly effective expert witness. He has testified at trial on 11 occasions, including three times in Federal court. Anthony is currently scheduled to testify in another seven trials during the next 18 months. Overall, he has been retained as an expert in over 60 matters related to water rights, water resources management, and water pollution. Anthony has provided deposition testimony in 27 of these matters and these depositions have lasted from one to 32 days in length.

Active:

- Retained (but not disclosed) in numerous cases (>200) related to the impact on water supplies by a group of emerging contaminants (consolidated in multi-district litigation [MDL])
- Lanier Parkway Associates vs. Hercules Chemical (Ashland) (the impact of benzene and chlorobenzene contamination from a chemical facility on an adjacent commercial property) – Superior Court of Glynn County, Georgia (expert affidavit)
- Retained (but not disclosed) by a confidential investor-owned water utility client addressing the impact of Per and polyfluorinated substances (PFAS) on water supplies in two northeastern states
- College Park East vs. Midway City Sanitary District et al (groundwater contamination by chlorinated solvents at a former dry cleaner) - US District Court, Central District of California (discovery)
- TC Rich et al vs. Shaikh et al (chlorinated solvent contamination at a former small batch chemical distributor in Los Angeles) - US District Court, Central District of California (expert report)
- Mojave Pistachios et al vs. Indian Wells Valley Groundwater Authority (IWVGA) (challenge to the Groundwater Sustainability Plan [GSP] and associated pumping fees in a groundwater basin in eastern Kern County) – California Superior Court, Kern County (discovery)
- James J. Kim vs. L. Tarnol et al (chlorinated solvent contamination at a former dry cleaner in Glendale) – California Superior Court, Los Angeles County (discovery)
- City of Oxnard v. Fox Canyon Groundwater Management Agency (water rights dispute) – California Superior Court, Los Angeles County (discovery)
- City of Arcadia vs. Dow Chemical et al (1,2,3-TCP contamination of groundwater resources and water supply wells) – US District Court, Central District of California (expert report)
- Friends of Riverside Airport vs. Department of the Army et al (poly-chlorinated biphenyl [PCB] contamination of soil at a former wastewater treatment plant in Riverside, California) US District Court, Central District of California (expert report, deposition)
- Stoll vs. Ewing et al (chlorinated solvent contamination at a former dry cleaner in Pleasanton) - US District Court, Northern District of California (discovery)
- San Luis Obispo Coastkeeper et al vs. Santa Maria Valley Water Conservation District et al (dispute over surface water flows to enhance steelhead habitat in the Santa Maria River watershed, Santa Barbara County) – US District Court, Central District of California (discovery)
- Mojave Pistachios vs. Indian Wells Valley Water District (IWVWD) et al (water rights dispute in eastern Kern County between agricultural interests and public water purveyors) – California Superior Court, Kern County (discovery)
- Goleta Water District vs. Slippery Rock Ranch (water rights dispute in central California between an avocado ranch adjacent to an adjudicated groundwater basin) – California Superior Court, Santa Barbara (expert report, deposition, trial scheduled for May 2021)

- Santa Barbara Channel-keeper et al vs. City of San Buenaventura et al (adjudication of surface water and groundwater rights in the Ventura River watershed, Ventura County) – California Superior Court, Los Angeles (expert report)
- Las Posas Valley Water Rights Coalition et al vs. Fox Canyon Groundwater Management Agency et al (adjudication of groundwater rights in the Las Posas Groundwater Basin, Ventura County) – California Superior Court, Santa Barbara (expert report, deposition pending, trial scheduled for 2022)
- Black Warrior Riverkeeper et al vs. Drummond Coal (acid mine drainage from a former coal mine impacting a tributary of the Black Warrior River, Alabama) – US Federal Court, Middle District of Alabama, Birmingham (expert report, deposition, trial scheduled for October 2021)
- City of Riverside vs. Goodrich et al (perchlorate contamination of groundwater resources and water supply wells) - California Superior Court (expert declaration, deposition, further deposition pending)
- Commonwealth of Pennsylvania vs. ExxonMobil, et al (State-wide assessment of impact and damages associated with MTBE and TBA releases) – US Federal Court, Southern District of New York (expert reports)
- State of Maryland vs. ExxonMobil et al (State-wide assessment of impact and damages associated with MTBE and TBA releases in Maryland) – US Federal Court, Southern District of New York (discovery)
- Steinbeck Winery et al vs. City of Paso Robles et al (Quiet title action brought by a group of wineries against the public water agencies to adjudicate water rights) - California Superior Court, San Jose (deposition, Phase 2 and Phase 3 trial testimony, Phase 4 pending)
- Various individuals vs. San Luis Obispo County et al (Trichloroethene [TCE] contamination in groundwater and water supply wells in a community adjacent to a County-operated airport) – California Superior Court, San Luis Obispo (litigation stayed)
- Commonwealth of Puerto Rico vs. Shell Oil Co., et al (Island-wide assessment of impact and damages associated with MTBE and TBA releases in Puerto Rico) – US Federal Court, Southern District of New York (expert report, deposition, trial pending)
- City of Fresno vs. Shell Chemical et al (1,2,3-TCP contamination of groundwater resources and water supply wells) – California Superior Court (discovery)
- New Jersey Department of Environmental Protection (NJDEP) vs. Sunoco et al (State-wide assessment of impact and damages associated with MTBE and TBA releases in New Jersey) – US Federal Court, Southern District of New York (expert report, deposition, hearing testimony, trial pending)
- Orange County Water District (OCWD) vs. Sabic Innovative Plastics et al (Chlorinated solvent, 1,4-dioxane and perchlorate contamination of groundwater resources from various sites in Orange County, California) – California Superior Court, Orange County (expert report, deposition [32 days], trial testimony)

- City of Modesto vs. Vulcan Chemical et al (perchloroethylene [PCE] releases from numerous dry cleaners contaminating drinking water wells and groundwater resources) – California Superior Court, San Francisco (expert reports, deposition [25 days], trial testimony, returned by Appeals Court)

Past:

- City of Upland vs. Dow Chemical et al (1,2,3-TCP contamination of groundwater resources and water supply wells) – US District Court, Central District of California (expert report, settled)
- Borrego Water District (water rights dispute and physical solution) – California Superior Court, San Diego (stipulated adjudication)
- Charleston Waterkeeper and South Carolina Coastal Conservation League vs. Frontier Logistics (lawsuit over polyethylene nurdle pollution in and around Charleston Harbor) - US District Court, Charleston District of South Carolina (expert report, settled)
- San Miguel Electric Cooperative vs. Peeler Ranch (contamination of soil, surface water and groundwater beneath a ranch from a lignite mine and coal-fired power plant) – Texas Superior Court, 218th District (expert report, deposition, hearing testimony, settled)
- City of Hemet vs. Dow Chemical et al (1,2,3-TCP contamination of groundwater resources and water supply wells) – US Federal Court, Southern District of California (expert report, settled)
- Sierra Club et al vs. Dominion Energy (contamination of groundwater and surface water resources by coal combustion residuals [CCRs] from ash ponds) – US Federal Court, Eastern District of Virginia (deposition, trial testimony)
- Sunny Slope Water Company vs. Dow Chemical et al (1,2,3-TCP contamination of groundwater resources and water supply wells) – California Superior Court, Los Angeles County (settled)
- Greenfield et al vs. Ametek Aerospace et al (solvent contamination in groundwater beneath three mobile home parks) – US Federal Court, Southern District of California, San Diego (expert report, deposition, settled)
- Golden State Water Company vs. Dow Chemical et al (1,2,3-TCP contamination of groundwater resources and water supply wells in Nipomo and Claremont) – US Federal Court, Southern District of California (expert report, settled)
- National Association for the Advancement of Colored People (NAACP) vs. Duke Energy (coal ash contamination of groundwater, sediments, and surface waters at the Belews Creek coal-fired power plant) – US Federal Court, Middle District of North Carolina (expert report, settled)
- City of Atwater vs. Shell Chemical et al (1,2,3-TCP contamination of groundwater resources and water supply wells) – California Superior Court (expert report, deposition, trial testimony)
- State of Vermont vs. ExxonMobil et al (State-wide assessment of impact and damages associated with MTBE and TBA releases in Vermont) – US Federal Court, Southern District of New York (settled)

- Trujillo et al vs. Ametek Aerospace et al (solvent contamination in groundwater beneath an elementary school) – US Federal Court, Southern District of California, San Diego (expert report, deposition, settled)
- Roanoke River Basin Association vs. Duke Energy (coal ash contamination of groundwater, sediments, and surface waters at two coal-fired power plants: Mayo and Roxboro) – US Federal Court, Middle District of North Carolina (expert report, deposition, settled)
- OCWD vs. Unocal et al (MTBE and TBA contamination of groundwater resources from service station sites in Orange County, California) – US Federal Court, Southern District of New York (expert report, deposition, settled)
- State of North Carolina vs. Duke Energy (administrative hearing related to coal ash contamination at six power plants) – North Carolina Superior Court (settled)
- City of Clovis vs. Dow Chemical et al (1,2,3-TCP contamination of groundwater resources and water supply wells) – California Superior Court (expert report, deposition, trial testimony)
- San Juan Hills Golf Course vs. City of San Juan Capistrano et al (suit filed over groundwater pumping in the San Juan Basin) – California Superior Court, Orange County (settled)
- City of Tulare vs. Dow Chemical et al (1,2,3-TCP contamination of groundwater resources and water supply wells) – California Superior Court (settled)
- State of California vs. Columbia Casualty Company et al (perchlorate and solvent contamination at the Stringfellow Acid Waste disposal pits in Glen Avon) – California Superior Court (expert report, settled)
- City of Delano vs. Crop Production Services (CPS) et al (Nitrate contamination of water supply wells) - California Superior Court (settled)
- Laborers' International Union of North America Local Union No. 783 v. Santa Margarita Water District et al. (Review of the groundwater hydrology of the Cadiz project, San Bernardino County) - California Superior Court, Orange County (independent expert report, settled)
- Southern California Water Company vs. Aerojet General Corp. (TCE, perchlorate and NDMA contamination of drinking water supplies in Rancho Cordova, California) – California Superior Court, Sacramento District (expert report, deposition, settled)
- The City of Stockton Redevelopment Agency (RDA) vs. Conoco-Phillips et al (petroleum hydrocarbon contamination at former oil terminals) – California Superior Court (deposition, settled)
- PK Investments vs. Barry Avenue Plating (hexavalent chromium and solvent contamination of soil and groundwater) - California Superior Court, Los Angeles District (deposition, settled)
- City of Santa Monica, California vs. Shell et al (MTBE contamination of drinking water supplies) – California Superior Court, Orange County District (expert report, deposition, settled)
- State of California vs. Joint Underwriters (perchlorate and solvent contamination at the Stringfellow Acid Waste disposal pits in Glen Avon) – California Superior Court (expert report, deposition, settled)

- Community of Broad Creek, North Carolina vs. BP Amoco et al (MTBE, benzene and 1,2-DCA contamination of private water supply wells) – North Carolina Superior Court (deposition, settled)
- South Tahoe Public Utility District, California vs. ARCO et al (MTBE contamination of drinking water supplies) - California Superior Court, San Francisco (expert report, deposition, trial testimony)
- Private well owners in 18 reformulated gasoline (RFG) states vs. various oil companies (class action related to MTBE) - US Federal Court, New York District (deposition, class certification hearing)
- Individual plaintiffs vs. Lockheed Corporation (TCE and perchlorate contamination of drinking water supplies in Redlands, California) – California Superior Court, Los Angeles District (deposition, settled)
- City of Norwalk vs. Five Point U-Serve et al (1.2-DCA contamination of a municipal drinking water well) – California Superior Court (deposition, case dismissed)
- Forest City Corp. vs. Prudential Real Estate (PCE contamination of soil and groundwater) – California Superior Court, Los Angeles District (deposition, trial testimony)
- Huhtamaki vs. Ameripride (chlorinated solvent contamination at a commercial dry cleaner/ laundry facility) – California Superior Court, Sacramento District (expert report, deposition, settled)
- Consolidated Electrical Distributors (CED) vs. Hebdon Electronics et al (chlorinated solvent contamination in fractured granite) - California Superior Court, North San Diego District (expert report, deposition, trial testimony)
- Southern California Water Company vs. various parties (water rights petition and adjudication for the American River, Sacramento, California) – State Water Resources Control Board, Sacramento
- The City of Santa Monica, California vs. ExxonMobil Corporation (MTBE contamination of drinking water supplies) – California Superior Court (designated, settled, retained as consultant to both parties for remedy implementation)
- The town of Glenville, California vs. various parties (MTBE contamination of drinking water supplies in Kern County, California) - California Superior Court (designated, settled)
- Great Oaks Water Company vs. Chevron and Tosco (MTBE contamination of drinking water supplies in San Jose, California) - California Superior Court (designated, settled)
- Orange County District Attorney's Office vs. ARCO et al (Underground Storage Tank [UST] violations, and MTBE contamination of soil and groundwater) - California Superior Court (designated, settled)
- Cambria Community Services District (CCSD) vs. Chevron et al (MTBE impact to drinking water supplies) in San Luis Obispo County, California - California Superior Court (designated, settled)
- Los Osos Community Services District (CCSD) vs. Chevron et al (MTBE impact to drinking water supplies) in San Luis Obispo County, California - California Superior Court (designated, settled)

- The town of East Alton, Illinois vs. various parties (MTBE contamination of drinking water supplies) – Illinois Superior Court, Jefferson County (designated, settled)
- The City of Dinuba vs. Tosco et al (MTBE contamination of groundwater resources) - California Superior Court (expert report, settled during deposition)
- Stella Stephens vs. Bazz-Houston et al (chlorinated solvent contamination at an active metal finishing facility in Garden Grove, California) - California Superior Court (designated, settled)
- Communities for a Better Environment (CBE) vs. Chrome Crankshaft (hexavalent chromium and TCE contamination beneath a chrome plating facility and adjacent school) - California Superior Court (designated, settled)
- California Attorney General's Office vs. Unocal (Natural Resource Damage Assessment [NRDA] at a former oil field in the central coast of California) - California Superior Court (designated, settled)
- Phillips Petroleum Corporation vs. private property owner (contamination from a former oil well in Signal Hill, California) - California Superior Court (designated, settled)
- Mobil Oil Corporation vs. private property owner (contamination from a former bulk fuel plant in the Bay Delta area) – California Superior Court (designated, settled)
- Mobil Oil Corporation vs. terminal operator (contamination from a former bulk fuel plant in Monterey area) – California Superior Court (designated, settled)

General Project Experience

Anthony has acted as the Principal in Charge, Project Manager (PM), Quality Assurance (QA) Manager and/or Principal Review for the following ongoing or recently completed projects:

Current Water Resources Projects

- Review of the Effect of Releases from a Reservoir on Surface Water Flows Intended to Enhance California Steelhead Habitat, and the Potential Impact on Groundwater Recharge – City of Santa Maria, Golden State Water Company
- An Investigation of the Hydrology of Perennial Spring in the Mojave Desert, as it Relates to Potential Impact from a Groundwater Resource Development Project - Three Valleys Municipal Water District
- Consulting Support Related to the Implementation of SGMA in the Pleasant Valley and Oxnard Plain Groundwater Basins, Pleasant Valley County Water District, Guadalasca Mutual Water Company.
- Consulting Support for a Surface Water and Groundwater Rights Dispute in the Ventura River Watershed – Group of Confidential Landowners
- Support Related to a New Car Manufacturing Plant in Huntsville, Alabama, and potential impact on habitat for an endangered species of fish – Center for Biological Diversity
- Review of the Groundwater Monitoring, Management, and Mitigation Plan (GMMMP) for the Cadiz Water Conservation Project – Three Valleys Municipal Water District

- Groundwater Consulting Support to an Agricultural Business in southeast Kern County Located within a Partially Adjudicated Basin – SunSelect
- Strategic Groundwater Consulting Support to a Large Golf Resort Located in a Desert Groundwater Basin Subject to Critical Overdraft under SGMA – Rams Hill GC
- Assessment of Water Resources at Oil Fields Throughout California and the Development of Produced Waters as an Alternate Water Supply – California Resources Corporation (CRC)
- Support Related to SGMA, Possible Adjudication, and Overall Groundwater Management Strategy for a Municipality in Southern California – Confidential Municipal Client
- Consulting Support for a Groundwater Rights Adjudication in the Las Posas Groundwater Basin, Ventura County – Group of Large Landowners
- Support Related to SGMA, Salinity Management, Alternate Water Sources, and Overall Groundwater Management Strategy for a Grower in the Bay-Delta – Wonderful Orchards
- Evaluation of the Feasibility of Using Brackish Groundwater and Oilfield Produced Water as an Alternate Water Supply for a Basin in Critical Overdraft – Northwest Kern Brackish and Oilfield (BOF) Water Study Group
- Support Related to SGMA, Possible Adjudication, and Overall Groundwater Management Strategy for a Large Water District in the Central Valley – Confidential Water District Client
- Water Rights Dispute Between a Water District and an Avocado Ranch in Central California – Slippery Rock Ranch
- Evaluation of the Feasibility of Using Brackish Groundwater as an Alternate Water Supply for a Closed Desert Basin in Critical Overdraft – Indian Wells Valley Brackish Water Study Group
- Development of a Plan for an Adjudication of Water Rights in a Desert Basin and the Principles of a Groundwater Management Plan (i.e., Physical Solution) – Confidential Water District Client
- Support Related to SGMA for Water Districts on the West Side of Kern County, Including the Creation of Defined Groundwater Management Areas – Westside District Water Authority
- Support to Agricultural Interests in the "White Areas" in Madera County with Respect to the Implementation of the California Sustainable Groundwater Management ACT (SGMA) – Madera County Farm Bureau
- Evaluation of Water Supply Options, Including New Water Supply Wells, for a Major Oilfield in West Fresno County – CRC
- Development of a Water Budget for a Baseline Period, and Evaluation of Native Safe Yield, Annual Operating Safe Yield, Historical Pumping, and Conditions of Overdraft as Part of a Water Rights Dispute in the Central Coast of California – City of Paso Robles
- Design and Permitting of an Aquifer Storage and Recovery (ASR) Project for Indirect Potable Reuse (IPR) of Tertiary Treated Municipal and Industrial Wastewater – City of Fresno
- Assessment of Increased Pumping at a Data Center and the Impact on Nearby Municipal Water Supply Wells in Charleston, South Carolina – Southern Environmental Law Center (SELC)

- Litigation Support and Development of Groundwater Management Approaches as an Alternative to Compliance with the Sustainable Groundwater Management Act – Confidential Water District Client, Southern California
- Groundwater Management Support to a Very Large Agribusiness with Over 170,000 Acres of Almonds, Pistachios, Mandarins, Pomegranates, and Grapes in the San Joaquin Valley - Wonderful Orchards
- Evaluation of Groundwater Conditions and Quality, and The Degree of Hydraulic Connection Between Groundwater Basins, as Part of a Water Rights Dispute in the Central Coast of California – City of Paso Robles
- Development of a Water Supply Well Drilling Ordinance and Valuation of Water Rights for a Confidential Municipality in Southern California
- Support for a Major Agricultural Interest with Holdings in Four Separate Groundwater Basins in Relation to the Implementation of SGMA – RTS Agribusiness
- Development of a New Water Supply Well Field, Including Compliance with California Division of Drinking Water (DDW) Policy 97-005 (Impaired Source Policy), and Evaluation of Groundwater Contamination at a Nearby Aerospace Facility – City of Torrance
- Evaluation of Aquifer Characteristics and Groundwater Conditions Related to the Reinjection of Oil Field Produced Water and Development of a Strategy to Obtain an Aquifer Exemption – Confidential Oil Company
- Development of a recycled water program (including possible aquifer storage and recovery [ASR]/salt-water intrusion program) using advanced treatment of a blend of brackish groundwater and urban storm-water – City of Santa Monica
- Membership of the Technical Advisory Committee (TAC) of a Cooperative Groundwater Group that will Become a Groundwater Sustainability Agency (GSA) – Indian Wells Valley
- Evaluation of Basin Hydrogeology, Groundwater Conditions, Water Quality, and Well Production in a Riparian Coastal Basin in Southern California – City of San Juan Capistrano
- Investigation and Development of Alternate Groundwater Supplies for an Agricultural Interest with Land Holdings in an Arid California Valley – Mojave Pistachios
- Development of a 50,000 acre-foot per year (AFY) ASR Project in the Eastern Portion of a Large Agricultural Valley in Southeast California – Confidential Client
- Review of the Groundwater Hydrology of the Cadiz Project – an independent expert report prepared for Orange County Superior Court in re: Laborers' International Union of North America Local Union No. 783 v. Santa Margarita Water District et al.

Petroleum Hydrocarbons

- Assessment of the Impact of MTBE/TBA Contamination of Water Resources in the State of Vermont, Including Contamination at Release Sites, Public Water Supply Wells, and Private Domestic Wells – State of Vermont

- Evaluation of Produced Water Management Options for Two Active Oil Fields in Southern California, including Treatment and Beneficial Use - CRC
- Assessment of the Impact of MTBE/TBA Contamination of Groundwater Resources in the State of Maryland, and Development of Costs to Address the Contamination at Release Sites, Public Water Supply Wells, and Private Domestic Wells – State of Maryland
- Investigation of Petroleum Hydrocarbon Contamination Related to Releases at a Pipeline that Crosses a Large Ranch in the Central Coast of California – Twin Oaks Ranch
- Assessment of Petroleum Contamination from a Large Pipeline Release that is Discharging to Two Streams and a Wetland in Belton, South Carolina – Southern Environmental Law Center (SELC)
- Evaluation of Contamination by Petroleum Hydrocarbons from a Pipeline Release at a Large Ranch/Winery in the Central Coast of California, and Development of a Conceptual Remedial Program and Costs to Implement – Santa Margarita Ranch, California
- Assessment of the Impact of MTBE/TBA Contamination of Groundwater Resources in the State of Pennsylvania, and Development of Costs to Address the Contamination at Release Sites, Public Water Supply Wells, and Private Domestic Wells – Commonwealth of Pennsylvania
- Investigation and Remediation of MTBE/TBA and Petroleum Hydrocarbon Contamination (using surfactant enhanced product recovery) at a Maintenance Facility in Hawthorne, California – Golden State Water Company
- Assessment of the Effectiveness of Site Investigation and Remediation Activities, Investigation of Off-Site Groundwater Contamination by MTBE/TBA, and Development of Remedial Programs (and Costs) at "Bellwether" Trial Sites - Orange County Water District
- Evaluation of Contaminant Conditions and Prior Site Investigation and Remediation Activity, Implementation of Off-site Investigations, and Development of Remedial Programs and Associated Costs to Address MTBE/TBA Contamination at Trial Sites in Puerto Rico – Commonwealth of Puerto Rico
- Assessment of Site Investigation and Remediation Activities, Investigation of Off-Site Groundwater MTBE/TBA Contamination, and Development of Remedial Programs (and Costs) at Trial Sites – New Jersey Department of Environmental Protection (NJDEP)
- Environmental Impact Report (EIR) and Baseline Environmental Assessment at a Proposed Oil Field Redevelopment Project, Southern Iraq - Confidential Client
- Development of a Remediation Approach and Costs for Soil and Groundwater Contamination at Two Former Petroleum Terminals – Stockton Redevelopment Agency
- Assessment of the Nature of Contamination and the Costs to Address this Contamination at a Former Municipal Landfill in San Diego County – Confidential Client
- Evaluation of Contaminant Sources, and the Fate and Transport of MTBE, 1,2-DCA and Benzene to Numerous Private Water Supply Wells in the Community of Broad Creek, North Carolina

- Assessment of the Effectiveness of Site Investigation and Remediation Activities to Address MTBE/TBA/Benzene Contamination at ARCO and Thrifty Service Stations Throughout Orange County, California - Orange County District Attorney's Office
- Evaluation of Contaminant Sources, Fate, Transport, and Impact of MTBE and TBA to Public Water Supplies, and the Costs to Treat these Contaminants, in the town of East Alton, Illinois
- Court Appointed Consultant to Develop Site Investigation Programs for MTBE/TBA/Benzene Contamination at 35 Thrifty Service Stations in Orange County
- Impact and Mitigation of Oil Field Contaminants at the Belmont Learning Center – Los Angeles Unified School District (LAUSD) - Belmont Commission
- Investigation, PRP Identification, Remediation and Restoration of Municipal Well Fields Impacted by MTBE Contamination – City of Santa Monica (Charnock Well Field), South Lake Tahoe Public Utility District (STPUD), Santa Clara Valley Water District (SCVWD), Great Oaks Water Company
- Oversight of Oil Company Investigation and Remediation Programs in Honolulu Harbor, Hawaii – US Environmental Protection Agency (USEPA)
- Assessment of Oil Field Contaminants in Relation to High Incidences of Leukemia and non-Hodgkins Lymphoma at a High School in Southern California – Confidential Client
- Evaluation of Fuel Releases and Their Impact upon Groundwater Resources at Service Stations, Bulk Plants, Fuel Terminals and Refineries Throughout California – Confidential Client
- Complete Restoration of Municipal Water Supply Wells Contaminated with MTBE – City of Santa Monica (Arcadia Well Field) and ExxonMobil Corporation
- Preliminary Environmental Assessment (PEA) at the Hull Middle School - located on a former oil field and landfill - Torrance Unified School District (TUSD), California
- Oversight of Investigation and Remediation Activities for a MTBE Release at a Service Station and the Potential Impact on a City's Water Distribution System – City of Oxnard, California
- Investigation of MTBE Contamination of Water Supply Wells and Other Petroleum Hydrocarbon Contamination at a Marine Fueling Depot on Catalina Island – Southern California Edison
- Impact of MTBE Releases at Service Stations and a Bulk Fuel Terminal on Drinking Water Wells and Groundwater Resources - City of Dinuba, California
- Oversight of a Court-ordered MTBE/TBA Plume Delineation Program at Gasoline Service Stations in Orange County, California – OCDA, California
- Oversight and Investigation of Remediation of MTBE Contamination Impacting Drinking Water Supplies in the Towns of Cambria and Los Osos/Baywood Park, California – Cambria Community Services District (CCSD), Los Osos Community Services district (LOCSD), Cal-cities Water Company
- Assessment of the Impact of an MTBE Release on Water Supply Wells, Sewers, and a Wastewater Treatment Plant – City of Morro Bay, California

- Investigation and Remediation of an MTBE Release in the Immediate Vicinity of a Drinking Water Supply Well - City of Cerritos, California
- Assessment of the Impact of Petroleum Hydrocarbon Contamination from a Wolverine Pipeline Release in Jackson, Michigan – Private Property Owner
- Investigation of Fuel Oil LNAPL and Hexavalent Chromium Contamination at a Former Clay Products Manufacturing Facility in Fremont, California – Mission Clay Products
- Assessment of the Impact of MTBE Releases on Water Supply Wells, and Oversight of Responsible Party (RP) Investigation and Remediation Activities - Soquel Creek Water District, California
- MTBE Contamination of Private Drinking Water Supplies and Development of Water Supply Treatment and Replacement Alternatives – Glenville, California
- Assessment of the Impact of MTBE on Drinking Water Supply Wells in Santa Clara County, California – Great Oaks Water Company (GOWC)
- Assessment of Data Gaps and Research Needs Regarding MTBE Impact to Water Resources – UK Environment Agency
- Investigation and Mitigation of the Impact of Oil Field Contaminants on a Large Apartment Complex in Marina del Rey, Los Angeles, California – Confidential Client
- Investigation and Remediation of Methane and Hydrogen Sulfide as Part of the Redevelopment of a Former Oil Field in Carson, California - Dominguez Energy/Carson Companies
- Assessment of Methane and Petroleum Hydrocarbon Contamination at a Former Oil Field in Santa Fe Springs, California – General Petroleum
- Natural Resource Damage Assessment (NRDA) at the Guadalupe Oil Field, California - State of California (Department of Fish and Game [DFG], Oil Spill Prevention and Response [OSPR], Attorney General and Regional Water Quality Control Board [RWQCB])
- Assessment of the Impact of Oil Field Activities on Surface Water and Groundwater Resources in the Central Coast of California – State of California
- Groundwater Investigation and Remediation at Four Petroleum Terminals in Wilmington, Carson, and San Pedro, California - GATX
- Research into Technologies for Treatment of MTBE in Water - Association of California Water Agencies (ACWA) / Western States Petroleum Association (WSPA) / Oxygenated Fuels Association (OFA)
- Characterization and Remediation of a Hydrocarbon Release (including MTBE) from a Refined Product Pipeline in Fractured Bedrock in Illinois – Shell
- Investigation and Remediation of Petroleum Hydrocarbon Contamination Beneath a City Maintenance Yard and City Bus Yard – City of Santa Monica, California
- Investigation and Remediation of a Gasoline Release (including MTBE) in Fractured Bedrock Resulting from a Catastrophic Tank Failure – Intrawest Ski Resorts, California

- Assessment of LNAPL, Aromatic Hydrocarbon, and Chlorinated Solvent Contamination Beneath a Former Waste Disposal Facility in Santa Fe Springs, California – Confidential Client
- Investigation of Soil and Groundwater Contamination at a Fueling Facility at a Municipal Airport – City of Santa Monica, California
- Pipeline Leak Investigation and Remedial Design - Mobil Pipeline, Ft. Tejon, California
- Investigation of a Petroleum Release in Fractured Bedrock - Chevron, Julian, California
- Contribution of Multiple Sources to Groundwater Contamination – Mobil Oil Corporation, La Palma, California
- Forensic Assessment of a Gasoline Release – Mobil Oil Corporation, Santa Monica, California
- Investigation of a Diesel Fuel Release – General Petroleum, Point Hueneme, California
- Service Station Investigations and Remediation (> 60 sites) - Mobil Oil Corporation, World Oil, Los Angeles County Metropolitan Transportation Authority (LACMTA), and Others
- Assessment of a Crude Release from a Former Pipeline - Mobil Oil, Gorman, California
- Remediation of 2,000,000-gallon (7,560 m^3) LNAPL Spill - Gulf Strachan Gas Plant, Alberta

Chlorinated Solvents

- Evaluation of Groundwater Contamination at an Aerospace Facility in El Cajon, the Threat to Water Supply Wells, and Vapor Intrusion Concerns at Overlying Properties – Confidential Client
- Investigation of Groundwater Contamination and Potential Sources for TCE Contamination in Groundwater and Water Supply Wells in a Community Adjacent to a County-Operated Airport – Confidential Client
- Evaluation of Poly-Chlorinated Biphenyls (PCBs) in Storm Water and the Impact on Groundwater Resources and the Use of Treated Storm Water for Aquifer Recharge and Saline Intrusion Barriers – Confidential Municipal Clients
- Assessment of the Effectiveness of Site Investigation and Remediation Activities, Investigation of Off-Site Groundwater Contamination, and Development of Remedial Programs (and Costs) at Solvent “Source Sites” in the South Basin Groundwater Protection Project (SBGPP) - Orange County Water District
- Consulting Support to a Community Adjacent to the Santa Susana Field Laboratory (SSFL), a Facility Previously Used to Test Rockets – Bell Canyon Homeowners Association
- Investigation of Groundwater Contamination by Perfluorinated Compounds (e.g., PFOA, PFOS) and its Impact on Public Water Supplies in Southeastern North Carolina – Confidential Client
- Investigation of Chlorinated Solvent and Petroleum Hydrocarbon Contamination, and Implementation of an Extended Remediation Pilot Study, at a Small-Batch Chemical Distribution Facility in Santa Fe Springs, California – Angeles Chemical Corporation

- Evaluation of Contaminant Distribution and Fate, and Development of a Remedial Approach and Costs, for Chlorinated Solvent Contamination in Groundwater at a Light Industrial Facility in Northridge, California, – Confidential Client
- Project Management Consultant (PMC) for the Hazardous Substances Account Act (HSAA) Program (i.e., State-CERCLA) as part of the SBGPP – Orange County Water District
- Assessment of Conceptual Hydrogeology and the Sources of 1,2-DCA and PCE Contamination of a Large Public Water Supply Well – Confidential Client
- Investigation and Remediation of Chlorinated Solvent Contamination in Soil and Groundwater Beneath a Metal Finishing Facility in Inglewood, California – Bodycote Hinterliter and Joseph Collins Estate.
- Investigation and Remediation of Soil and Groundwater Contamination at a Former Wood Treating Facility – Port of Los Angeles
- Assessment of the Nature of PCE Releases from Dry Cleaning Facilities, the Impact Upon Groundwater Resources, and the Cost of Remediation – City of Modesto, California
- Investigation of Chlorinated Solvent Contamination in Soil, Groundwater and Drinking Water Supplies Beneath Various Facilities in Lodi, California – Confidential Client
- Investigation of TCE and Hexavalent Chromium Contamination at the Suva School in Montebello, California – Communities for a Better Environment
- Remediation of Chlorinated Solvents, Including Vinyl Chloride, in Soil and Groundwater Beneath a Former Aerospace Facility in West Los Angeles, California – Playa Vista Capital
- Assessment of Chlorinated Solvent and Hexavalent Chromium Contamination at an Active Metal Finishing Facility in the City of Garden Grove, California – Confidential Client
- Investigation and Remediation of Hexavalent Chromium and TCE Contamination at an Active Plating Facility in West Los Angeles – confidential client
- Contamination of Drinking Water Supplies by TCE and Perchlorate from an Aerospace Manufacturing Facility in Redlands, California – Individual Plaintiffs
- Investigation and Remediation of Hexavalent Chromium, TCE, and Gasoline LNAPL Contamination at an Active Plating Facility in Santa Fe Springs, California – Confidential Client
- Investigation and Remediation of Hexavalent Chrome and TCE Contamination at the Los Angeles Academy (formerly Jefferson) Middle School, Los Angeles, California – Jefferson Site PRP Group
- Evaluation of Groundwater and Contaminant Conditions at an Active Municipal Landfill in Los Angeles County, California – Browning Ferris Industries (BFI)
- Investigation of Chlorinated Solvent Contamination in Groundwater Beneath a Municipal Airport – City of Santa Monica, California
- Resource Conservation and Recovery Act (RCRA) Facility Assessment and Closure for a Large Aerospace Facility in Hawthorne, California – Northrop Grumman Corporation

- Characterization of Complex Hydrogeology and Contaminant Fate and Transport (with Poly-chlorinated Biphenyls [PCBs] and Chlorinated Solvents) in Karstic Bedrock at a Site on the National Priority List (NPL) in Missouri – MEW PRP Steering Committee
- Design of a Groundwater Remediation Program for Chlorinated Solvent, Perchlorate and Other Contaminants Utilizing Existing Drinking Water Wells – San Gabriel Valley Water Company (SGVWC)
- Investigation of a Chlorinated Solvent Release in Fractured Bedrock – Consolidated Electrical Distributors, San Diego, California
- Contamination of Drinking Water Supplies by TCE from an Aerospace Manufacturing Facility in Redlands, California – Individual Plaintiffs
- Investigation of a Chlorinated Solvent Release at an Active Chemical Terminal - GATX, San Pedro, California
- Technical and Regulatory Assistance, and RP Oversight and Review, Chlorinated Solvent Contamination Beneath a Former Aerospace Facility – City of Burbank, California
- Investigation and Remedial Design for a Chlorinated Solvent Release at an Active Machine Shop – Mighty USA, Los Angeles, California
- Remediation of Chlorinated Solvents in Groundwater as Part of a Rail Freight Transfer Terminal Development - Port of Los Angeles, California
- Remedial Evaluation of PCE Contamination at a Former Scientific Instruments Manufacturing Facility – Forest City, Irvine, California
- Evaluation of a Chlorinated Solvent Release at a Dry Cleaners - Los Angeles City Attorney, West Los Angeles, California
- Assessment of a Chlorinated Solvent Release from Former Dry Cleaners – DeLoretto Plaza, Santa Barbara, California
- Characterization and Remediation of LNAPL at an Active Chemical Refinery - ICI, Teeside, UK

Perchlorate

- Investigation of Regional Perchlorate Contamination of Groundwater Resources in the Central Basin of Los Angeles – Water Replenishment District of Southern California (WRD)
- Investigation of regional groundwater contamination by perchlorate in the Rialto-Colton, Bunker Hill, and North Riverside Basins, and impact to water supply wells – City of Riverside
- Assessment of the Effectiveness of Site Investigation and Remediation Activities, Investigation of Off-Site Groundwater Contamination, and Development of Remedial Programs (and Costs) at Perchlorate Release Sites in the South Basin Groundwater Protection Project (SBGPP) - Orange County Water District
- Hydrogeologic Investigation, Source Identification, Water Supply Well Impact Assessment, and Drinking Water Treatment for Perchlorate – City of Morgan Hill, California
- Evaluation of the Fate and Transport of Perchlorate and NDMA Contamination and its Impact on Water Supplies in Rancho Cordova, California – Southern California Water Company

- Hydrogeologic Investigation, Water Supply Well Impact Assessment, Regulatory Assistance, and Responsible Party (RP) Oversight for Perchlorate Contamination – City of Gilroy, California
- Regulatory and Technical Assistance, RP Oversight and Review, Water Resource Impact Assessment for Perchlorate Contamination – City of Santa Clarita, California
- Design of a Groundwater Remediation Program for Chlorinated Solvent, Perchlorate and Other Contaminants Utilizing Existing Drinking Water Wells – San Gabriel Valley Water Company (SGVWC), San Gabriel Valley Superfund Site, California
- Evaluation of the Off-site Migration of Perchlorate and TCE Contamination from a Rocket Testing Facility in Simi Hills, California – City of Calabasas, County of Los Angeles
- Investigation of Potential Perchlorate Source Sites, Source Contribution, Contaminant Pathway Assessment, and Drinking Water Treatment – Fontana Water Company, West Valley Water District, Fontana, California
- Evaluation of Previous Environmental Investigations, Contaminant Transport and Remediation Options for Perchlorate and Solvent Contamination at the Stringfellow Acid Waste Disposal Pits in Glen Avon, California – Joint Underwriters

Hexavalent Chromium

- Investigation and Remediation of Hexavalent Chrome and TCE Contamination at the Los Angeles Academy (formerly Jefferson) Middle School, Los Angeles – Jefferson Site PRP Group
- Investigation and Remediation of Hexavalent Chromium and TCE Contamination at an Active Plating Facility in West Los Angeles – Confidential Client
- Hydrogeologic Investigation of Hexavalent Chromium Contamination in the Northern Area of the Central Basin in Los Angeles County – Water Replenishment (WRD)
- Investigation of TCE and Hexavalent Chrome Contamination at the Suva School in Montebello, California – Communities for a Better Environment
- Investigation of Fuel Oil LNAPL and Hexavalent Chromium Contamination at a Former Clay Products Manufacturing Facility in Fremont, California – Mission Clay Products
- Investigation and Remediation of Hexavalent Chromium, TCE, and Gasoline LNAPL Contamination at an Active Plating Facility in Santa Fe Springs California – Confidential Client

Other Projects

- Investigation of the Source, Magnitude, Extent and Fate of Polyethylene Nurdle Pollution in and Around Charleston Harbor – Charleston Waterkeeper and South Carolina Coastal Conservation League
- Review and Critique of Proposed Coal Ash Pond Closure at the Tennessee Valley Authority (TVA) Gallatin Power Plant - SELC
- Evaluation of Surface Water and Groundwater Pollution by Boron and Other Metals and Salts Associated with Coal Ash at Georgia Power's Plant Scherer Generating Station - SELC

- Assessment of the Impact of 1,2,3-TCP Contamination from Soil Fumigant Applications on Municipal Water Supplies – City of Arcadia
- Investigation of PCB Contamination at a Former Wastewater Treatment Plant at a Former US Army Camp – City of Riverside
- Investigation of the Fate, Transport, and Persistence of 1,2,3-TCP Contamination of Groundwater and Municipal Water Supply Wells – City of Upland
- Assessment of Sediment, Surface Water, and Groundwater Contamination Associated with Coal Ash at the Belews Creek Coal-Fired Power Plants in North Carolina, and an Evaluation of Closure Options for Coal Ash Basins – NAACP
- Assessment of the Impact of 1,2,3-TCP Contamination from Soil Fumigant Applications on Municipal Water Supplies – Sunny Slope Water Company
- Investigation of Sources and Fate and Transport of 1,2,3-TCP Contamination in Groundwater and its Impact on Potable Water Supply Wells in and around the City of Claremont – Golden State Water Company
- Evaluation of disposal and/or treatment options for produced waters at three active oil fields in Kern County – California Resources Corporation
- Assessment of 1,2,3-TCP Contamination of Groundwater and Potable Water Supply Wells in the Nipomo Area of Central California – Golden State Water Company
- Evaluation of potential water resources impacts from a proposed coal ash landfill located within a flood plain near Laredo Texas – confidential ranch owner
- Investigation of the Fate, Transport, and Persistence of 1,2,3-TCP Contamination of Groundwater and Municipal Water Supply Wells – City of Hemet
- Investigation of elevated concentrations total dissolved solids (TDS) and dissolved metals in surface water and groundwater related to an active lignite mine and coal-fired power plant at a large ranch in southeast Texas – Peeler Ranch
- Assessment of soil, groundwater, and surface water contamination associated with a Former Manufactured Gas Plant (MGP) in South Carolina – Southern Environmental Law Center (SELC)
- Evaluation of Contaminated Groundwater and Surface Waters by 1,4-dioxane, Perfluorinated Compounds [PFCs], and Gen-X at a Chemical Manufacturing Facility in North Carolina – Cape Fear Riverkeeper
- Investigation of 1,2,3-TCP Contamination of Groundwater and Municipal Water Supply Wells – City of Fresno
- Evaluation of Surface Water, Sediment, and Groundwater Contamination and Assessment of Remedial Actions at a Former Manufactured Gas Plant in South Carolina – Confidential Client
- Evaluation of Flow Conditions and Water Quality in Surface Water and Groundwater at an Active Coal-Fired Power Plant in North Carolina, including Three-Dimensional Groundwater Flow and Solute Transport Modeling – Sierra Club

- Assessment of 1,2,3-TCP Contamination of Groundwater Resources and Water Supply Wells in Clovis, California, and Development of Well-head Treatment Programs and Associated Costs - City of Clovis
- Investigation of Surface Water and Groundwater Impacted by Acid Mine Drainage (AMD) from a Former Coal Mine in Alabama, Including Geophysical Mapping, Piezometer Installation, and Soil, Sediment, and Surface Water Sampling – Black Warrior Riverkeeper
- Evaluation of Groundwater and Surface Water Contamination by Coal Combustion Residuals (CCRs) from Ash Ponds at Power Generation Facilities in Eastern Virginia – Sierra Club
- Investigation of 1,2,3-TCP Contamination of Groundwater and Municipal Water Supply Wells – City of Atwater
- Evaluation of Contaminant Sources and Hydrogeologic Pathways for 1,2,3-TCP Contamination of Water Supply Wells - City of Tulare
- Identification of Potential Sources of Nitrate Contamination at a Municipal Water Supply Well – Water Replenishment District of Southern California (WRD)
- Assessment of Sediment, Surface Water, and Groundwater Contamination Associated with Coal Ash at Two Coal-Fired Power Plants in North Carolina, and an Evaluation of Closure Options for Coal Ash Basins – Roanoke River Basin Association
- Assessment of the Volume and Quality of Storm Water and Shallow Groundwater (from Dewatering) at a Large Condominium Complex, as part of a City's MS-4 Storm Water Permitting – Coronado
- Investigation of Nitrate Contamination of Groundwater Resources and Water Supply Wells in Delano, California, and Development of Well-head Treatment Programs and Associated Costs - City of Delano
- Evaluation of Contaminant Conditions and Closure Plans for Coal Ash Basins at Two Coal-Fired Power Plants in Virginia – Sierra Club
- Evaluation of Groundwater and Surface Water Contamination by CCRs from Ash Ponds at a Former Power Generation Facility in Central Virginia – Sierra Club and Potomac Riverkeeper
- Negotiation of Private Agreements Between Water Utilities and RPs – City of Santa Monica, STPUD, City of Morro Bay, SGVWC, GOWC, City of Oxnard, OCDA
- Evaluation of Power Plant Intake and Outfall Structures on Fecal Coliform Plume Dynamics and Resulting Beach Closures, Huntington Beach, California – California Energy Commission
- Investigation of Bacteria and Fecal Contamination in Groundwater Beneath the Downtown Area of Huntington Beach, California – City of Huntington Beach
- Investigation of the Source(s) and Transport of Enterococcus and Fecal Bacteria to the Near Shore Waters of Huntington Beach, California – City of Huntington Beach, County of Orange, Orange County Sanitation District (OCSD)
- Characterization and Remediation, Former Town Gas Sites - British Gas Properties, U.K.
- Aquifer Characterization, Contaminant Assessment, Slurry Wall Design and Installation, Soil Excavation and Water Treatment System Design - Port of Los Angeles, California

Professional History

aquilogic, Inc., CEO and Principal Hydrologist, 2011 to present.
exp, Executive Vice-President, Chief Business Development Officer, 2010 to 2011
WorleyParsons, Senior VP, Strategy & Development, 2006 to 2010.
Komex Environmental Ltd., Chief Executive Officer, Principal Shareholder, Director, 1999 to 2005.
Komex•H2O Science•Inc., President and Principal Hydrologist, 1992 to 1999.
Remedial Action Corporation, Project Manager and Geohydrologist, 1989 to 1992.
Lanco Engineering, Project Manager, 1985 to 1987, and 1988.
Royal Geographical Society, Kosi Hills Resource Conservation Project, Nepal: Project Director, 1983 to 1985

Teaching

Anthony has recently taught the following classes:

- Environmental Aspects of Soil Engineering and Geology - a ten-week course at the University of California, Irvine
- Site Characterization and Remediation of Environmental Pollutants - two lectures as part of the course at Imperial College London
- Methyl Tertiary Butyl Ether: Implications for European Groundwater - a one day seminar for the UK Environment Agency (UKEA)
- Successful Remediation Strategies – a two-day course for the NGWA
- Understanding Environmental Contamination in Real Estate, and one day class for the International Right-of-Way Association (IRWA)
- Project Development and the Environmental Process, a one-day class for the IRWA
- Environmental Awareness, a one-day class for the IRWA
- Regional Fuels Management Workshop, a two-day workshop for the USEPA.

Publications

In addition to his teaching experience, Anthony has prepared over 1000 written project reports, and has written, presented and published many articles regarding the following:

- The implementation of the SGMA in California
- Groundwater law in California
- The development of alternate water supplies, notably brackish groundwater
- Aquifer storage and recovery and other groundwater augmentation actions
- The Clean Water Act and groundwater contamination
- Contamination of groundwater and drinking water supplies by fuel oxygenates, chlorinated solvents, rocket propellants, PFCs, and metals
- Contaminant fate and transport in fractured or heterogeneous media
- The impact of oil field activities on the environment

- Source water assessment and protection
- Public health and toxicology
- Risk analysis and assessment
- Environmental economics
- General water resources and environmental issues

The following is a list of publications and presentations:

Brown, A., 2021. Science in the Court Room: Expert Witness Testimony in Contamination Cases. American Groundwater Trust California PFAS Webinar, March 2021.

Brown, A., 2021. Sources of 1,2,3-TCP and its Persistence in California Groundwater. American Groundwater Trust 1,2,3-TCP Webinar, February 2021.

Brown, A., 2020. Groundwater and the Clean Water Act. American Groundwater Trust California Groundwater Conference, Ontario, February 2020.

CURRICULUM VITAE

October 2021

Robert H. Abrams, PhD, PG, CHg

Principal Hydrogeologist

mobile: +1.650.743.0594
email: bob.abrams@aquilogic.com

Disciplines

Hydrogeology, Water Resources, Geology, Geostatistics, Analytical and Numerical Modeling, Water Quality, Groundwater and Vadose Zone Fluid Flow, Contaminant Fate and Transport.

Education

Ph.D. Hydrogeology, Stanford University, 1999
M.S. Hydrogeology, Stanford University, 1996
B.S. Geology, San Francisco University, 1991

Professional Registrations

Professional Geologist, CA (No. 8703)
Certified Hydrogeologist, CA (No. 931)
Licensed Geologist, North Carolina (No. 2639)

Professional Experience

Bob has over 20 years of professional experience in groundwater resource development, groundwater sustainability, groundwater banking, groundwater quality, and model design and evaluation. He has worked for the California Geological Survey, the U.S. Geological Survey, Stanford University, San Francisco State University, consulting firms, and as an independent consultant for public and private clients. Recent projects have included vadose zone characterization and modeling, evaluation of subsidence investigations, developing and reviewing integrated groundwater/surface water hydrologic models that include simulation of current and future land-use-based water demand and the impact of climate change, and preparation of Groundwater Sustainability Plans.

Project Experience

Summary of California Central Coast Projects

- Currently serving on the Seawater Intrusion Working Group (SWIG) and SWIG Technical Advisory Committee (TAC). Theses groups are tasked with evaluating and recommending approaches for mitigating seawater intrusion in the 180/400-Foot Aquifer Subbasin – *Salinas Basin Groundwater Sustainability Agency, Carmel Valley, California, representing the Salinas Basin Water Alliance*.

- Currently serving on a Drought Technical Advisory Committee (TAC) charged with developing standards and guiding principles for determining release schedules and operations of Nacimiento and San Antonio reservoirs during multiyear droughts. The TAC is also charged with developing the release schedules during such droughts – *Monterey County Water Resources Agency, Salinas, California, representing Grower-Shipper Association of Central California.*
- Invited to participate in the Deep Aquifer Roundtable, a formal meeting attended by Salinas Valley hydrogeology experts to discuss approaches to monitoring and protecting the deepest portions of the Salinas Valley aquifer system – *Monterey County Water Resources Agency, Salinas, California*.
- Served on the Technical Advisory Committee for the development of the Salinas Valley Integrated Hydrologic Model, a new MODFLOW model constructed by Monterey County and the U.S. Geological Survey – *Monterey County Water Resources Agency, Salinas, California representing Grower-Shipper Association of Central California*.
- Well efficiency test results for multiple years and multiple wells were evaluated for a Salinas Valley grower and food processor. Quantitative and statistical analyses were used to assess well performance and make recommendations for potential well maintenance and repair activities – *Nunes Vegetables, Salinas, California*.
- The factors influencing nitrate concentrations in well-water from approximately 60 wells on 40 ranches were determined and an enhanced groundwater monitoring program was developed. Diverse and complex data sets were analyzed statistically and qualitatively to understand the geologic, hydrologic, and anthropogenic factors that variably influence well-water concentrations over short- and long-term timeframes. Specific recommendations for wellhead protection were also developed – *Costa Farms, Analysis of Observed Nitrate Concentration Trends in Irrigation Wells, Soledad, California*.
- Published reports and data from international and national seawater intrusion mitigation efforts were reviewed and analyzed. The analysis was to assess the feasibility, level of effort required, volumes of water necessary, and costs of implementation in the Salinas Valley of a seawater intrusion injection barrier using recycled water. Ongoing injection barrier projects in Orange County and L.A. County were selected for in-depth review to evaluate the feasibility of a similar project in Monterey County – *Tanimura & Antle, Salinas, California*.
- Publicly available groundwater quality data from a set of regularly sampled water-supply wells were evaluated statistically to develop an alternative to installation of new monitoring wells for a land application area that received wastewater from a food processing plant. The effort was driven by a Central Coast Regional Water Quality Control Board order requiring client to participate in the General Waste Discharge Requirements (WDRs) for Fruit and Vegetable

Processors, which has stricter monitoring requirements than the previous individual WDRs – *Dole Fresh Vegetables, Salinas, California*.

- Evaluated (with SEAWAT) the degree to which irrigation wells were drawing seawater inland and if groundwater withdrawals contributed to anoxic conditions in certain reaches of a river hydraulically connected to the aquifer – *El Sur Ranch, Seawater Intrusion and Impact of Irrigation Wells, Monterey County, California*.
- Monte Carlo hydraulic gradient analysis and stochastic 1D and 2D solute transport simulations (analytical solutions) were conducted based on regional groundwater maps and 13 years of monthly groundwater levels from dozens of production wells to determine the most likely MTBE source areas. A customized GIS framework was developed to evaluate source-area probability. Accepted by the Central Coast Regional Water Quality Control Board – *Monterey County Water Resources Agency, Salinas MTBE Investigation, Salinas, California.*
- Conducted a technical evaluation and provided detailed comments regarding the hydrologic analysis undertaken for the draft environmental impact report/environmental impact statement for the proposed Monterey Peninsula Water Supply Project (MPWSP) - *Third-Party Evaluation of Hydrologic Analysis Conducted for Monterey Peninsula Water Supply Project, City of Marina, California*.

Summary of Selected Recent Projects

- Designed and wrote custom computer programs to construct and test a facsimile of the USGS Central Valley Hydrologic Model (CVHM) that runs in Groundwater Vistas (GV), a graphical user interface. The computer programs generated input data for the facsimile model from CVHM MODFLOW packages that are not supported by GV. The facsimile model produces results that are nearly identical to CVHM – *Confidential Client*.
- Combined vadose-zone flow and transport modeling, groundwater flow modeling, and particle-tracking simulations to estimate the persistence of dissolved 1,2,3-trichloropropane in the subsurface. Multiple application areas were characterized using lithologic logs and water flux out of the root zone taken from C2VSimFG Beta. Custom computer programs were written to determine arrival time at a declining water table. MODFLOW and MODPATH were used to estimate travel time from the water table to receptor water-supply wells. Four regions in California (one in Central Valley, three in Southern California) were successfully analyzed with this methodology (settlements and jury awards). For the Central Valley region, the CVHM facsimile model (described above) was used – *Confidential Clients*.
- Co-wrote the Chapter Groundwater Sustainability Plan for the Westside Water Authority in Kern County. Extremely sparse data and modeling results from C2VSimFG-Kern were used to estimate current and future water budgets and groundwater availability – *Westside Water Authority*.

- Conducted environmental impact assessment simulations using the CVHM facsimile model described above to evaluate drawdown and subsidence caused by a proposed brackish groundwater water treatment project in Kern County – *Westside Water Authority*.
- Critically evaluated subsidence estimates along the Tule Subbasin portion of the Friant-Kern Canal (FKC) by reviewing historical USGS reports, InSAR data, geomechanical modeling, and the Tule Subbasin Groundwater Flow Model. This evaluation indicated that responsibility for FKC subsidence should be shared across the subbasin and not focused primarily on the Eastern Tule Groundwater Sustainability Agency – *Confidential Client*.
- Critically evaluated groundwater flow and solute transport models for three coal ash disposal sites in North Carolina. Primary questions included if the models simulated flow and transport properly and sufficiently to allow the sites' owner to claim no offsite groundwater quality impacts above water quality standards – *Southern Environmental Law Center*.
- Developed a new IWFM groundwater-surface water model, based on the Central-Valley-wide C2VSim model, for Stanislaus County to assess impacts in terms of foreseeable land-use changes and installation of new wells – *Stanislaus County, Regional Groundwater-Surface Water Model for PEIR, Modesto, California.*
- Assist Stanislaus County with evaluation of new major well permit applications based on a then-recently passed groundwater ordinance requiring evaluation under CEQA for potential pumping-induced impacts to the groundwater basin, such as lowered water levels in existing wells, land subsidence, and significant groundwater or surface water depletion – *Stanislaus County, Well Permit CEQA Analysis, Modesto, California*.

Summary of Other Selected Water Supply Projects

- Two local-scale groundwater flow (MODFLOW) and solute transport models (MT3DMS) were developed for two sub-regions of the USGS regional Antelope Valley MODFLOW model to evaluate the performance of a new groundwater bank. Updated geologic characterization was based on recent investigations by the USGS and sparse well logs. Groundwater bank performance was evaluated with respect to water quantity and quality for various operational strategies, including well placement and infiltration schedules – *Antelope Valley-East Kern Water Agency (AVEK), Groundwater Banking and Blending Study, Palmdale, California.*
- Developed and calibrated three-dimensional, groundwater flow (MODFLOW) and solute transport models (MT3DMS) to assess water sources for a new 20 MGD water treatment plant. A detailed geologic model was developed for this project to assess the extent of the deep target aquifer, evaluate the risk from a heavy industrial area, well locations, long-term performance, define the wellhead protection area, and optimize wellfield performance – *City of Longview, Design and Construction of a New Groundwater Source and Treatment Facility, Longview, Washington.*
- Pilot study to evaluate the feasibility of compressed air energy storage of renewable energy. Developed and implemented three-dimensional groundwater flow models (MODFLOW) to

evaluate the impact on nearby wells of compressed air injection into a depleted natural-gas reservoir – *Pacific Gas and Electric (subcontractor to Jacobson James and Associates), Compressed Air Energy Storage Pilot Project, San Joaquin County, California.*

- Developed hydrostratigraphic model of the Mesquite Lake groundwater subbasin as interpreted from existing well logs and USGS studies that had been performed to the west and north. The hydrostratigraphic model was used as input to a three-dimensional, transient groundwater flow model (MODFLOW) that assessed the volume of water available for a new municipal water treatment plant – *Twentynine Palms Water District, Groundwater Study for the Mesquite Lake Subbasin, Twentynine Palms, California.*
- Developed a calibrated two-dimensional, steady-state analytical groundwater flow model for the Rialto-Colton Basin. The calibrated model was used to delineate source areas for two impacted production wells for a CDPH 97-005 permit application – *West Valley Water District, Wellhead Treatment Project, Rialto, California.*
- Analyzed the results of aquifer tests of multiple water supply wells completed in a fractured-rock aquifer – *Lake Don Pedro Community Services District, California (subcontractor to SGI The Source Group)*.
- Analyzed the results of a complex aquifer-test dataset to determine aquifer properties and assess groundwater availability. Characterized groundwater quality and assessed regional impact of developing a new water supply – *Silver Oak Cellars (subcontractor to Taber Consultants), Aquifer Test Analysis and Groundwater Availability Study, Sonoma County, California.*
- A well and a spring were evaluated in terms of water quality, influence of surface water, source area, and zone of influence for a license application to operate a new private water supply – *Buster's on the Mountain (subcontractor to Taber Consultants), Hydrogeology Report for New Private Water Supply, Napa County, California*.
- Groundwater flow modeling, aquifer test results, and qualitative hydrogeological analyses were reviewed and critiqued for accuracy and completeness to assess the feasibility of a gravel mining operation adjacent to the upper reaches of a major river in Los Angeles and Ventura counties. The assessment formed the basis for communications with the State Water Resources Control Board regarding appropriative water rights. In the second phase of the project, a new MODFLOW model was developed to assess groundwater-surface water interactions – *Confidential Client (subcontractor to Todd Engineers), Groundwater Pumping Impacts on Streamflow, Los Angeles County, California.*
- Developed complex geologic model in the fold-thrust terrane of the Las Posas Basin in eastern Ventura County. The geologic model formed the foundation for preliminary wellfield design and estimation of available groundwater for desalter operations in a strictly managed aquifer – *Calleguas Municipal Water District, Somis Desalter Feasibility Study, Las Posas Basin, Ventura County, California*.

- Evaluated geologic, hydrologic, and hydrogeologic data to assess the suitability for establishing a groundwater banking operation. Provided recommendations on further field-based and modeling studies deemed necessary to address data and knowledge gaps – *Los Angeles Department of Water and Power, Evaluation of Proposed Water Storage/Transfer Potential in Fremont Valley Basin, Fremont Valley, California.*
- Evaluated the groundwater component of an existing water-budget model. Implemented changes to include the effects on water levels from climate and distant municipal pumping in deeper parts of the aquifer. The improvements facilitated the development and simulation of future "what-if" scenarios used to design an engineered wetland that used stormwater runoff and groundwater pumping to maintain lake levels – *San Francisco Public Utilities Commission, Lake Merced Water-Budget Model, San Francisco, California.*

Summary of Other Selected Water Quality Projects

- Developed three-dimensional, variably saturated flow and reactive transport models (MODFLOW-SURFACT) to assess the groundwater impact from arsenic and boron in recharged partially treated oilfield produced water. Transport through the unsaturated and saturated zones related to groundwater banking operations were simulated. Regulatory approval was granted by the Central Valley Regional Water Quality Control Board – *Cawelo Water District, Groundwater Banking Waste Discharge Requirements Support, Central Valley, California*.
- A calibrated transient three-dimensional model (MODFLOW and MT3DMS) of groundwater flow and solute transport was developed, calibrated, evaluated, to compare estimated timeframes to achieve RAOs for three alternatives. Site data were used to characterize the subsurface and estimate land application rates and water quality of applied water. Regulatory approval was granted by the Central Valley Regional Water Quality Control Board – *Hilmar Cheese Company, Groundwater Modeling for Cleanup and Abatement Order, Central Valley, California.*
- The results of two modeling efforts were reviewed to reassess contributions from responsible parties. A new metric, the Responsibility Factor (RF), was developed and applied to existing input data. The RFs were used to estimate relative contributions to the MEW Superfund site regional plume from several responsible parties – *Confidential Client (subcontractor to Montclair Environmental Management), Reassessment of Contributions to the MEW Superfund Site Regional Plume, Santa Clara County, California.*
- Mass flux calculations for TCE and PCE were conducted on behalf of a multi-PRP group. Calculations of mass flux through time were compared upgradient and downgradient of several sites within the Omega Superfund site regional plume to estimate the contribution from each individual site. These calculations were used as part of the basis for cost allocation among PRPs – *Confidential Client, Mass Flux Calculations for Cost Allocation, Omega Superfund Site, Santa Fe Springs, California.*
- A three-dimensional model (MODLFOW-SURFACT) of unsaturated zone and saturated zone flow and solute transport was developed and calibrated based on sparse discharge records

and well observations to assess the fate of a legacy of contaminated soil water being mobilized by increased discharge to the subsurface. The modeling was an integral part of a report of waste discharge and request for waste discharge requirements from the Central Valley Regional Water Quality Control Board – *California Dairies, Incorporated, Report of Waste Discharge, Central Valley, California.*

- A transient groundwater flow model (MODFLOW) was conceptualized, implemented, and calibrated for a major oil refinery. Linear programming was used to quantitatively minimize groundwater pumping and qualitatively optimize well placement for containment of subsurface LNAPL and BTEX-contaminated groundwater. Multiple capture zones of various sizes were analyzed for control of LNAPL hotspots and site-wide containment scenarios – *Sun Oil Company, Pumping-Rate Optimization and Capture Zone Analysis, Tulsa County, Oklahoma.*
- A groundwater flow and reactive solute transport model (MODFLOW and RT3D) was developed to evaluate remediation efforts at a chemical production facility. The efficacy of a permeable reactive barrier was evaluated by simulating sequential decay and transport of TCE and its daughter products. The model was post-verified in the field by analyzing the concentration histories of several observation wells – *Mohawk Laboratories, Analysis of Permeable Reactive Barrier, Sunnyvale, California.*
- Determined regional-scale risk to groundwater from potentially contaminating activities (PCA) in the Santa Clara Valley, Coyote, and Llagas subbasins, as part of a multifaceted effort. A regional-scale PCA-risk map was developed and combined with intrinsic aquifer sensitivity to generate a groundwater vulnerability map, which formed the basis of a web-based GIS tool for evaluating development projects and land-use changes – *Santa Clara Valley Water District, Groundwater Vulnerability Study, Santa Clara, California.*
- A Remedial Investigation (RI) Summary report was prepared under CERCLA guidelines, which included development of a conceptual model that incorporated regional and local hydrostratigraphy, source-area history, details of previous remedial investigations, and characterization of the basin-wide perchlorate and TCE groundwater contamination – *West Valley Water District, NCP Compliance Documents, Rialto, California.*
- The volume of LNAPLs beneath a refinery was estimated by modifying the analytical solutions for LNAPL recovery presented within API Publications 4682 and 4729, utilizing the van Genuchten relations for porous media. Results of the modeling work were used to design a LNAPL recovery system – *Sun Oil Company, LNAPL Spatial Distribution, Tulsa County, Oklahoma.*
- DNAPL Assessment Techniques, Klickitat County, WA. Developed internal White Paper describing techniques and thresholds for assessing DNAPL mobility at a fueling facility – *BNSF, Remediation Design Support, Park County, Montana*.
- Report of waste discharge and request for waste discharge requirements for land application of onsite waste and storm water. For submission to the Los Angeles Regional Water Quality Control Board – *Confidential Client, Report of Waste Discharge, Los Angeles County, California.*

- Developed and implemented groundwater flow and particle tracking models to evaluate well placement designs and optimize pumping rates for an in-situ groundwater recirculation and treatment zone. The recirculation zone was used to chemically treat groundwater contaminated with VOCs – *BNSF, Remediation Design Support, Park County, Montana.*
- Analyzed slug test data for multiple tests using several techniques to assess parameter uncertainty for a bedrock aquifer, for submission to Montana Department of Environmental Quality – *BNSF, Site Characterization for Remedial Investigation, Park County, Montana.*
- A 1D unsaturated zone flow and transport model was developed to assess the impact to groundwater of VOCs and metals present in the soil at the Facility. A future 100-year scenario was developed based on climate data from the past 100 years. Mass transport process of volatilization, linear sorption, and advection and dispersion were considered for this investigation – *SMTEK, Former Chemical Facility, Orange County, California.*

Summary of Other Selected Litigation Support Projects

- Implemented detailed regional, three-dimensional conceptual model for a 35-year period (MODFLOW and MT3DMS). Geologic data, crop-based time-variant DBCP application rates, pumping, recharge basins, and flow and transport in the unsaturated and saturated zones were used to evaluate whether label-recommended use of DBCP caused contamination in municipal wells and to establish likely source areas for high-concentration hot spots – *Sedgwick, Detert, Moran, and Arnold, Regional-Scale Pesticide Contamination Litigation Support, Fresno, California.*
- Designed and implemented three-dimensional models (LEACHM, MODFLOW, and MT3DMS) of unsaturated and saturated fluid flow and solute transport for periods of up to 150-years using soils and geologic data, rainfall records, pumping, and plant operational history to assess whether off-site groundwater contamination was caused by unanticipated releases of coal tar at numerous sites in the Midwest – *Jones, Day, Reavis, and Pogue, Former Manufactured-Gas Plant Sites, Litigation Support, Los Angeles, California.*
- The impact of different rainfall data disaggregation techniques on the results of fluid flow and solute transport simulations in the unsaturated zone was evaluated. Various disaggregation strategies were applied to simulations of contaminant fate at three former manufactured-gas plants – *Northern Indiana Public Service Company, Impact of Rainfall Data Disaggregation Techniques, Merrillville, Indiana.*
- Evaluated expert reports and thoroughly evaluated and verified a detailed water budget model. Assisted in preparation of expert report related to the application of the model – *Confidential Client, Water Budget Model Litigation Support, Pinal County, Arizona*.
- Evaluated expert reports and critiqued a detailed MODFLOW groundwater flow model for litigation of damages and fatalities from a landslide. Assisted in preparation of expert report – *Confidential Client, Landslide Initiation Litigation Support, British Columbia.*

Stanford University, Research Associate, September 2000 to July 2002
Independent Consultant/Graduate Student, October 1995 to July 2000.
U.S. Geological Survey/Graduate Student, Hydrologist, June 1992 to September 1995.

Research

- A new protocol and computer code were designed and implemented to simulate the development of redox zones in contaminated aquifers. Transport of dissolved constituents coupled to complex interactions between organic and inorganic compounds were simulated with consideration of reaction energetics, reaction-rate limitations, and advection and dispersion – *Stanford University/United States Geological Survey, Development and Fate of Redox Zones in Contaminated Aquifers, Falmouth, Massachusetts*.
- Interactions between surface water, soil-water, and groundwater were evaluated with a three-dimensional model of coupled saturated-unsaturated subsurface and surface fluid flow. Detailed rainfall data were incorporated into the model to determine the relative importance of different stormflow generation mechanisms – *Stanford University, Stormflow Generation, Chickasha, Oklahoma*.
- Conducted basin-scale modeling analysis of subsurface fluid flow in the Illinois Basin to evaluate the role of paleogroundwater flow versus fluid density in long-range, deep-basin petroleum migration – *United States Geological Survey, Basin-scale Analysis of Subsurface Fluid Flow, Illinois Basin*.
- Developed reactive solute transport models to evaluate zinc transport in a geochemically complex aquifer in Falmouth, MA. Coupled solute transport/geochemical modeling, laboratory experiments, and a two-site surface complexation model were used to represent the pH-dependent adsorption of dissolved zinc on aquifer sediments – *United States Geological Survey, Zinc Transport in a Geochemically Complex Aquifer, Falmouth, Massachusetts*.

Statements in the Salinas Valley Basin Groundwater Sustainability Agency (SVBGSA) Groundwater Sustainability Plans (GSPs) establishing that the six Salinas Valley subbasins are interconnected.

- Upper Valley – Forebay boundary:
  - Page 4-10 of the draft Upper Valley GSP: "*There are no reported hydraulic barriers separating these subbasins and therefore the GSP needs to consider potential for groundwater flow between these adjacent subbasins*."
  - Page 4-10 of the draft Forebay GSP: "*There are no reported hydraulic barriers separating these subbasins*."
- Forebay – 180/400 boundary:
  - Page 4-10 of the draft Forebay GSP: "*There is no reported hydraulic barrier between the Forebay and the 180/400-Foot Aquifer Subbasin however the sediments are more stratified in the 180/400-Foot Aquifer Subbasin than in the Forebay Subbasi*n."
  - Page 4-9 of the 180/400 GSP: "*Previous studies of groundwater flow across this boundary indicate there is reasonable hydraulic connectivity with the Forebay Subbasin, although the principal aquifers change from relatively unconfined to confined near this boundary*."
- Forebay – Eastside boundary:
  - Page 4-10 of the draft Forebay GSP: "*The northwestern boundary with the adjacent 180/400-Foot and Eastside Aquifer Subbasins generally coincides with the southeastern limit of confining conditions in the 180/400-Foot Aquifer Subbasin, which is extrapolated to the Gabilan Range to define the boundary with the Eastside Aquifer Subbasin (DWR, 2004c)*."
  - Page 4-10 of the draft Eastside GSP: "*The southeastern boundary with the adjacent Forebay Subbasin is near the town of Gonzales (DWR, 2004). It is extended from the approximate southern limit of the regional clay layers that are the defining characteristic of the southern extent of the 180/400-Foot Aquifer Subbasin. There may be reasonable hydraulic connectivity with the Forebay Subbasin, although the principal aquifers change from relatively unconfined to confined near this boundary*."
    - The last sentence of this passage appears to be incorrect, as indicated on page 4-18 of the draft Eastside GSP: "*In addition to the fact that aquifer material cannot be correlated between boreholes, no evidence exists for a discrete confining layer in the Subbasin (Brown and Caldwell, 2015)*."
    - Further supporting evidence for hydraulic connection between the Eastside and Forebay is found on page 4-21 of the draft Eastside GSP: "*Subsurface recharge is primarily from inflow from the adjacent Forebay and 180/400-Foot Aquifer Subbasins to the south and west, respectively (DWR, 2004). This inflow is*

estimated to be 17,000 acre-feet (AF) on an annual basis. Total natural recharge is estimated to be 41,000 AF (DWR, 2004)."

- Eastside – 180/400 boundary:
  - Page 4-21 of the draft Eastside GSP: "*Subsurface recharge is primarily from inflow from the adjacent Forebay and 180/400-Foot Aquifer Subbasins to the south and west, respectively (DWR, 2004). This inflow is estimated to be 17,000 acre-feet (AF) on an annual basis. Total natural recharge is estimated to be 41,000 AF (DWR, 2004)*."
  - Also, on page 4-35 of the draft Eastside GSP: "*There is no recorded seawater intrusion in the Eastside Subbasin. Even though it is adjacent to the 180/400-Foot Aquifer Subbasin where seawater intrusion is occurring, the Subbasin, which is approximately 7 miles from the coastline, is not yet affected by seawater intrusion. However, there is a potential for seawater intrusion into the Subbasin*."
  - Page 4-10 of the draft Eastside GSP and page 4-9 of the 180/400 GSP: "*Previous studies of groundwater flow across this boundary indicate that there is restricted hydraulic connectivity between the subbasins*."
    - The references for the previous studies should be provided because this statement is an apparent contradiction with other statements in the draft Eastside GSP.
    - Furthermore, page ES-8 of Kennedy/Jenks (2004) states, "*We note that ground water flow direction is from the Pressure Subarea to the East Side Subarea east of the City of Salinas and along the transition zone (Agency 1997*)."
    - Additionally, page 8 of SVGWBHC (1995) states, "*Ground water can move between the East Side and Pressure Areas, and between the Forebay and Pressure Areas, the Forebay and East Side Areas, and the Upper Valley and Forebay Areas*."
    - The apparent uncertainty regarding the nature of the boundary between the Eastside and 180/400 should be listed as an identified data gap on page 4-35 of the draft Eastside GSP.
- Eastside – Langley boundary:
  - Page 4-10 of the draft Eastside GSP and page 4-10 of the draft Langley GSP: "*Although the Langley Subbasin is not on the valley floor, there are no reported hydraulic barriers separating these subbasins and therefore the GSP needs to consider potential for groundwater flow between these adjacent subbasins*."
- Langley – 180/400 boundary:
  - Page 4-10 of the draft Langely GSP: "*Although the Langley Subbasin is not on the valley floor, there are no reported hydraulic barriers separating these two subbasins; therefore, this GSP needs to consider potential for groundwater flow between these adjacent subbasins*."
  - Page 4-9 of the 180/400 GSP: "*Although the Langley Subbasin is not on the valley floor, there are no reported hydraulic barriers separating these two subbasins*."
- Monterey – 180/400 boundary:

- Page 9 of Chapter 4 of the draft Monterey GSP: "*The northeastern boundary with the 180/400-Foot Aquifer Subbasin is divided into two parts: the northern part coincides with a buried trace of the Reliz Fault (DWR, 2016); the southern part follows the contact between Aromas Sand / Paso Robles Formations (Qae/QT) and alluvium (Q). The Reliz Fault does not appear to be a barrier to groundwater flow between these subbasins (see Section 4.2.3)*."
- Page 4-9 of the 180/400 GSP: "*Although a groundwater divide is commonly found near the Subbasin boundary, there is potential for groundwater flow between these two subbasins*."
- It should be noted that for the simulations reported in Chapter 6 of the draft Monterey GSP, all reasonably possible boundary conditions, indicate groundwater flow from the Monterey to the 180/400.

MEMORANDUM

To: Stephanie Hastings, Brownstein Hyatt Farber Schreck (BHFS)
Sent via email: SHastings@bhfs.com
From: Robert H. Abrams, PhD, PG, CHg, Principal Hydrogeologist, aquilogic, Inc.
Anthony Brown, CEO & Principal Hydrologist, aquilogic, Inc.

Subject: **Assessment of Groundwater Flows between Subbasins of the Salinas Valley Groundwater Basin (SVGB)**
Project No.: 018-09

Aquilogic, Inc. (**aquilogic**) is pleased to provide this memorandum on behalf of our mutual client, the Salinas Basin Water Alliance (SBWA), outlining the justification and necessity for conducting additional simulations with the Salinas Valley Integrated Hydrologic Model (SVIHM),[1] which is being used by the Salinas Valley Basin Groundwater Sustainability Agency (SVBGSA) for groundwater sustainability plan (GSP) development.

Aquilogic hypothesizes that pumping has captured significant portions of groundwater discharge that would otherwise migrate as underflow from the Upper Valley Subbasin to the Forebay Subbasin, from the Forebay Subbasin to the 180/400-Ft Aquifer Subbasin and East Side Subbasin, and potentially from the 180/400-Ft Aquifer Subbasin to the Monterey Subbasin and the Salinas River. Our primary concern is that the existing water budget analyses in at least three of the SVBGSA's draft GSPs may not provide a complete picture of the downgradient impacts caused by groundwater pumping.[2]

It should be noted that groundwater sustainability was a pertinent issue for water managers long before the advent of California's Sustainable Groundwater Management Act. There is

ample support in the groundwater literature for considering multiple aspects of sustainability and undesirable results, including economic and social impacts and the contravention of water rights.[3]

ADDITIONAL SIMULATIONS

As stated in "SVIHM Frequently Asked Questions,"[4] one of the many questions that can be addressed by a model is: How much groundwater flows between subareas? Clearly, the SVIHM developers recognized the importance of this question and anticipated that it would be asked. On behalf of the SBWA, **aquilogic** requests that the SVBGSA utilize the SVIHM to conduct additional simulations that are specifically focused on the issue of inter-subbasin groundwater flows. The requested simulations will enable an improved understanding of the amount of Valley-wide groundwater discharge that is and has been captured by pumping, which may be needed to ensure the adequacy of the GSPs for each of the subbasins and important to their implementation.

Aquilogic recommends a type of "superposition" analysis, in which the results of two simulations are compared. In such an analysis, the two simulations are identical except for the process under examination, in this case groundwater pumping. Pumping would be selectively turned off in one simulation and left as currently configured in the SVIHM in the other simulation. A similar superposition analysis was done to assess pumping-induced streamflow depletion, as described in Chapter 5 of the GSPs for the Forebay Subbasin and the East Side Subbasin.

The inter-subbasin flows would then be compared, which would semi-quantitatively estimate the impact of pumping, within the limiting assumptions and uncertainties associated with the SVIHM. Ideally, the analysis should be conducted with the initial conditions of the no-pumping scenario representing a "full" SVGB. The analysis would provide an estimate of the impact of pumping on inter-subbasin groundwater flows.

Specifically, using the calibrated SVIHM historical model, **aquilogic** recommends the following outline for conducting simulations, the details of which would be worked out in consultation with the SVBGSA:

1. Develop reasonable initial conditions for the hydraulic head distribution for the no-pumping simulation. This entails turning off all pumping in the model domain while

[4] https://www.co.monterey.ca.us/home/showdocument?id=31292

leaving all other inflows and outflows unchanged. Because the time for simulated water levels to recover may be longer than the SVIHM simulation period of 51 years (1967-2018), the simulation may have to be run multiple times before an average steady-state condition can be achieved. In this case, the hydraulic head distribution at the last time step of the previous simulation would be used as the initial condition of the subsequent simulation. This process would be repeated until the hydraulic head distribution at the last time step of a subsequent simulation is substantially identical to the last time step of the previous simulation. This would indicate that an average steady-state condition is being simulated. We assume here that the surface water inflows and reservoir releases for the 1967-2018 period would be sufficient to eventually "refill" the SVGB after several model runs.

2. When the average, no-pumping steady-state condition has been achieved with the modified SVIHM, simulated groundwater flow should occur from the East Side Subbasin to the 180/400-Ft Subbasin, and from the 180/400-Ft Subbasin to Monterey Bay, conditions that are now reversed.

3. From the final results of the no-pumping simulation, in which average steady-state conditions have been achieved, compute the inter-subbasin groundwater flows between each adjoining subbasin. Compare these flows with the inter-subbasin flows from the historical, unmodified SVIHM. The differences in inter-subbasin flows and induced recharge from the surface water system represent a semi-quantitative estimate of the impact of Valley-wide pumping.

4. Additional superposition analyses can be conducted to assess the impact of one subbasin's pumping on basin-wide groundwater levels and inter-subbasin groundwater flows, by turning on pumping in one subbasin at a time in the modified SVIHM (and leaving pumping turned off in all other subbasins) and comparing the results to the scenario with no pumping throughout the SVGB. The differences in inter-subbasin flows and groundwater levels represent a semi-quantitative estimate of the impact of one subbasin's pumping on the other subbasins.

Mr. Les Girard
Agency Counsel
Salinas Valley Basin Groundwater Sustainability Agency
168 W. Alisal Street, 3rd Floor
Salinas, CA 93901

SUBJECT: OPINIONS ON SURFACE WATER BENEFITS FROM SALINAS VALLEY GROUNDWATER SUSTAINABILITY

Dear Mr. Girard:

You have requested our opinion with respect to the benefit surface water users (including those that rely upon diversion of any alleged underflow of the Salinas River) would receive from a balanced or sustainable groundwater basin. This request is in connection with the proposal of the Salinas Valley Basin Groundwater Sustainability Agency's (SVBGSA) consideration of charging a regulatory fee, known as the Groundwater Sustainability Fee ("Fee"), within its jurisdiction (the Salinas Valley Groundwater Basin (Basin) with limited exceptions).

As you know, the firm I work for, Montgomery & Associates, has been retained by the SVBGSA to prepare a Groundwater Sustainability Plan for the 180/400 ft. aquifer sub-basin. In particular, I have been retained as the project manager for this job. My resume is enclosed. I am familiar with the hydrology and geology of the Basin, and the interaction between groundwater and surface water in the Basin.

It has long been acknowledged that the water resources of the Salinas Valley consist of an integrated surface water and groundwater system. Historically, groundwater was the main source of water supply in the Valley and the Salinas River was the primary source of recharge for the groundwater supply (see, for example, Department of Water Resource Bulletin 52B). This assessment of a single water, integrated water source was recently confirmed in the January 2019 Report of Referee by the State Water Resources Control Board, issued as part of a reference proceeding arising from litigation in the Basin. In particular, Page 12 of the report states, "The dependency on the Salinas River as a source of recharge for the Basin and the hydrologic connection between surface water and groundwater results in a direct relationship between pumping and river flows; therefore, demonstrating that groundwater and surface water within the Salinas Valley constitute a single source." This is consistent with, and corroborates my understanding of the Salinas Valley hydrology.

This acknowledged surface water/groundwater integration underpins the approach the SVBGSA is taking to achieving groundwater sustainability throughout the Valley; the

Salinas River is an integral part of groundwater management and managing groundwater cannot be divorced from the Salinas River's operations. Similarly, groundwater management plays an important role in maintaining Salinas River flows. Larger areas of low groundwater levels in the Salinas Valley will induce more leakage from the Salinas River – reducing Salinas River flows. Maintaining adequately high groundwater levels will help maintain Salinas River flows. These higher groundwater levels that help maintain Salinas River flows is one of the desired outcomes of our groundwater management and is a benefit to surface water users. Groundwater sustainability can lead to long-term reliability in surface water supplies.

In particular, one Sustainability Indicator that must be addressed under SGMA is depletion of surface water bodies. Without the Sustainable Groundwater Management Act (SGMA), there is limited or no check on the amount that groundwater pumping can deplete the Salinas River. Developing these GSPs provides an opportunity for groundwater to be managed in a way the benefits surface water users and provides surface water reliability.

Groundwater management may be the most effective and primary method for managing future surface water reliability in the Valley. The two dams operated by the Monterey County Water Resources Agency (MCWRA are not operated for surface water reliability. The MCWRA website states that the operational pools of the Nacimiento and San Antonio Dams are for "groundwater recharge, fish passage, and operation of the Salinas valley Water Project." The dams are not necessarily operated to maintain flows in the Salinas River.

Based on our review of the integrated groundwater and surface water system in the Salinas Valley we conclude that users of surface water, including underflow, would receive clear benefits from groundwater sustainability because:

- The Salinas River has historically been viewed as primarily a source of groundwater recharge, not as an independent source of supply;
- The two dams operated by MCWRA are not operated to provide reliable surface water supplies;
- Managing groundwater levels can reduce surface water depletions, providing more reliable surface water supplies;
- Addressing surface water depletion and the resulting surface water flows is a required component of the GSPs;

The Salinas River operations, Salinas River flows, and ability to use water from the River will be clearly influenced by the decisions made during GSP development and implementation. Balanced groundwater management that maintains consistent groundwater levels will provide surface water reliability for the Valley's surface water users.

Finally, it is important to note that, for purposes of charging the Fee, the Salinas River has not yet been determined to include a "subterranean stream flowing through known and

MONTGOMERY & ASSOCIATES

definite channels," thus the surface water/groundwater integration in the Basin makes it difficult to differentiate between the two where they interface. Thus, differentiating a fee based on whether surface water or groundwater is being pumped along that interface would be an extremely difficult, if not impossible, task.

Derrik Williams

Sincerely,
Derrik Williams
E.L. MONTGOMERY & ASSOCIATES

Derrik Williams, P.G., C.Hg., Principal Hydrogeologist/Director of California Business Development

Office: PASO ROBLES

Years Experience

Total: 30

Education

M.S., Hydrology, University of Arizona (1987)

B.S., Geology, University of California at Davis (1982)

Key Areas of Expertise

Groundwater basin management

3D groundwater flow and transport models

Groundwater recharge

Conjunctive water management

Aquifer test analysis

Interagency negotiation and coordination

Independent technical review

Derrik has more than 30 years of experience in applied geology and hydrogeology and excels at assisting clients with integrating technical analyses and institutional challenges to manage their water resources. His project experience includes managing, reviewing, and assisting on water supply, groundwater recharge, wastewater disposal, and hazardous waste remediation projects. Derrik is accomplished in analytical hydrogeology, with extensive interpretation and application of groundwater flow and transport models. He is an expert in aquifer test design and analysis and is experienced in all aspects of groundwater management.

Representative Projects

Water Resource Planning | Groundwater Management

SGMA Implementation • California Department of Water Resources •
Assisted DWR develop best management practices (BMP) for implementing SGMA and assist with developing Groundwater Sustainability Plans (GSPs). Met with DWR regularly to formulate statewide SGMA policy and draft policy documents. Helped develop DWR's guidance document for sustainable management criteria which was scheduled for release September 2017. **[SACRAMENTO COUNTY, CA]**

Basin Boundary Modification • Santa Margarita Groundwater Basin Boundary Modification • Scotts Valley Water District
Managed one of the most complex basin boundary modifications for SGMA's implementation. The basin boundary modification included both technical and jurisdictional modifications to promote sustainable groundwater management. Reviewed and interpreted relevant SGMA regulations for the client and hosted meetings with DWR and SWRCB to review and obtain agreement to the modification approach. Developed the technical justification to establish a new groundwater basin that encompasses all or parts of two existing groundwater basins, along with areas previously not considered groundwater basins. Assisted the client with required stakeholder outreach and water agency notification, and developed responses to concerns raised by neighboring water agencies. Presented the modification approach and technical work at numerous Boards of Directors meetings in Santa Cruz County. Directed the development of a 3D flow model to project groundwater inflow and dewatering requirements for a proposed gold mine **[SANTA CRUZ COUNTY ,CA]**

SGMA Support • SGMA Hydrology Tech Support • Santa Cruz Mid-County Groundwater Agency
Provides senior guidance for technical and policy support to the Groundwater Sustainability Agency (GSA) for the Santa Cruz Mid-County Basin regarding SGMA. This included the GSA formation process and an approved basin boundary modification that combined parts of four basins into a single basin

Professional Registrations

Registered Professional Geologist #6044, CA

Certified Professional Hydrogeologist #35, CA

Additional Training

Awards and Distinctions

and excluding areas that do not impact groundwater management. Led efforts with the newly formed GSA to finalize a schedule and scope for GSP development. The initial activities include presentations at stakeholder workshops to ensure all stakeholders understand the basin conditions and the requirements of SGMA. [SANTA CRUZ COUNTY, CA]

Groundwater Sustainability Agency Assessment • Butte County GSA Formation • Butte County Department of Water and Resource Conservation
Provided technical assistance regarding GSA development to Butte County as a subconsultant to Kearns and West Inc. Assisted Butte County assess the potential interest and concerns of various agencies and groups regarding GSA formation under SGMA. Helped develop the outreach materials to ensure that relevant information was collected to guide Butte County's GSA development. [BUTTE COUNTY, CA]

Groundwater Management • Seaside Basin Groundwater Management • Seaside Basin Watermaster
Helped develop both a Basin Management Action Plan and Seawater Intrusion Response Plan (SIRP) for the Watermaster in Monterey County. The Basin Management Action Plan identified specific data needs, water sources, and groundwater management actions and recommended an implementation strategy to the Watermaster. The SIRP was a companion document that included exhaustive statistical and graphical analyses of groundwater quality data to identify potential seawater intrusion. [MONTEREY COUNTY, CA]

Groundwater Management for the Soquel-Aptos Basin • General Hydrology • Soquel Creek Water District
Updated the groundwater management plan, investigated conjunctive use alternatives, provided well master plan EIR support, designed and installed monitoring wells, seawater intrusion monitoring, assisted with municipal well rehabilitation and restoration, and assisted with negotiating with neighboring agencies. [SANTA CRUZ COUNTY, CA]

Hydrologic Modeling | Groundwater Management

Managed Groundwater Model Update • Groundwater Model • Kings River Conservation District
Managed the groundwater model update for the Kings River Conservation District. The model is based on the State of California's Integrated Water Flow Model (IWFM). Important aspects of this model update include a reinterpretation of agricultural water demands throughout the region, and an update of the geologic structure that underpins the model. In particular, the client requested that the updated model parameters more accurately reflect our understanding of the basin's geologic structure. [FRESNO COUNTY, CA]

Lead Modeler • Seaside Basin Groundwater Model • Seaside Basin Watermaster
Served as project manager and lead modeler for the recently completed regional Seaside Basin groundwater model. The model was developed for the Seaside Groundwater Basin Watermaster. The model accurately simulates 22 years of historical water levels across a 76 square mile area near Monterey, California. An extensive update of the basin hydrostratigraphy was needed during the development phase of the model. The model is designed to compare benefits

for various potential groundwater management actions planned to be carried out in the basin. [MONTEREY COUNTY, CA]

Technical Analysis • Regional Groundwater Model • United Water Conservation District
Provided technical oversight for an update of United Water Conservation District's regional groundwater model. The model was providing unrealistic results, and was unable to predict future conditions adequately. Identified simulated water balance problems that, when changed, improved model performance dramatically. Provided technical assistance to staff on using the model to evaluate water management alternatives by implementing various hydrologic scenarios in model runs. [VENTURA COUNTY, CA]

Groundwater Model Support • Groundwater Basin Water Supply Plan and Groundwater Model • Squaw Valley Public Service District (SVPSD)
Provided groundwater support to the SVPSD continuously since 2000, beginning with development of a basin-wide groundwater model that could be used for management and planning. As SVPSD's needs have changed, adapted the initial model to help address new concerns. Under Derrik's direction, the project team has studied groundwater management alternatives as the main option in a plan to increase the water supply. They have used the groundwater flow model to support the water supply analyses. The model has also been used to develop pumping strategies that maximize long-term basin yield, and to identify locations of new wells that the SVPSD may use to increase their water supply. [PLACER COUNTY, CA]

Basin Analysis • Basin Management Plan Analysis • Pajaro Valley Water Management Agency
Led analysis of groundwater management alternatives for Pajaro Valley Water Management Agency's (PVWMA) Basin Management Plan. Directed simulation of alternatives using the Pajaro Valley Hydrologic Model developed by the U.S. Geological Survey that incorporated the Farm Process program, which allows detailed and realistic simulations of agricultural pumping and water transfers. Evaluated and presented model results for the BMP's selected alternative that showed that the alternative will eliminate overdraft in the most productive aquifers and reduce seawater intrusion by more than 90% in those aquifers. [SANTA CRUZ COUNTY, CA]

Developed Numerical Groundwater Model • Groundwater Model • Los Osos Community Services District
Developed a water and nitrate balance of the basin, accounting for all known water recharge and nitrate sources. Incorporated the water and nitrate balance into a numerical groundwater model, used to predict future groundwater conditions. The model showed that the proposed sewer system significantly lowers nitrate levels in the shallow aquifer. Nitrate was shown to be migrating towards municipal wells, however, and will continue to impact these wells for decades into the future. [SAN LUIS OBISPO COUNTY, CA]

Impact Analysis • Groundwater Impact Analysis • San Benito County Water Agency | City of Hollister
Investigated groundwater impacts from changing wastewater quality in San Benito County. Helped develop, calibrate, and use a groundwater model of San Benito County to estimate groundwater impacts and changing salt loads near

the wastewater treatment ponds and at anticipated reclaimed water application sites. The modeling was used to develop alternative strategies to manage both salt loading and high groundwater levels. [SAN BENITO COUNTY, CA]

Developed Transport Model • Charnock Initial Regional Response Activities (CIRRA) Modeling • Environ Corporation
Helped develop and use a basin-wide flow and transport model for the Charnock Sub-Basin in Los Angeles County. Served as a senior consultant for this project, helped develop and guide the modeling program, calibrated the groundwater model, and provided quality assurance and quality control on the modeling process. [LOS ANGELES, CA]

Developed Groundwater Model • Regional Groundwater Flow Model • Santa Clara Valley Water District
Developed a groundwater flow model of the Northern Santa Clara Valley under a joint contract between the City of San Jose and the Santa Clara Valley Water District. The model is presently used by the SCVWD for future water planning. [SANTA CLARA COUNTY, CA]

Model Analysis • San Francisco Western Basin Groundwater Model • San Francisco Department of Public Works
Provided an independent review of the San Francisco Western Basin groundwater model. Produced a plan for field testing and expanding the groundwater model to include the influence of groundwater pumping in Daly City, Colma, and Burlingame on Lake Merced water levels. [SAN FRANCISCO COUNTY, CA]

Water Supply and Recharge | Groundwater Resource Development

Well Siting Study • SCWA Groundwater Assessment • Sonoma County Water Agency
Completed a well siting study for Sonoma County Water Agency's Reliability Assessment. Integrated hydrogeologic analyses of potential well sites with information on geologic hazards and existing and proposed water transmission facilities to identify optimum well locations. [SONOMA COUNTY, CA]

Designed Irrigation Wells • Golden Gate Park Replacement Wells • City of San Francisco
Managed the Golden Gate Park Replacement well project as part of a joint venture. Worked with the Department of Public Works and the Public Utility Commission to site and design two new irrigation wells. The irrigation wells were designed to meet DPW's goal of an assured water supply, while allowing PUC to use the wells as emergency potable supply. [SAN FRANCISCO COUNTY, CA]

Quantification of Interflow • Creek/Aquifer Interaction Study • Squaw Valley Public Service District (SVPSD)
Directed a unique study to establish and quantify the interflow between Squaw Creek and the adjoining shallow aquifers. The study used temperature monitoring techniques that directly estimate the flow rates between the Creek and the shallow aquifers. This project was funded by a California Department of Water Resources AB303 Local Groundwater Assistance Grant. [PLACER COUNTY, CA]

Water Supply and Recharge | Recharge & Recovery

Developed ASR System • Coastal Water Project Aquifer Storage and Recovery (ASR) • ASR Systems
Assisted with development of the ASR component of the Coastal Water Project (CWP) along the Monterey Peninsula. Helped design an ASR system that will provide peak flows to supplement supplies from the planned Moss Landing desalination plant and developed a groundwater model of the target injection zone, based on initial injection test results. [MONTEREY COUNTY, CA]

Feasibility program management • ASR Feasibility Study Management • Squaw Valley Public Service District (SVPSD)
Provided oversight of the field program that included a surface geophysical survey and installation of a monitoring well with a Sonic continuous coring rig. Reviewed the feasibility report that concluded that a suitable water storage interval for ASR in Squaw Valley is not present. [PLACER COUNTY, CA]

Developed Cost Estimates • ASR Well Costs • Sonoma County Water Agency
Developed well cost estimates for the groundwater banking program as part of a water supply EIR. Costs were developed for both new and retrofitted ASR wells. [SONOMA COUNTY, CA]

Technical Analysis • Water Supply Improvement Program • East Bay Municipal District
Coordinated the project, and performed technical analysis for the Water Supply Improvement Program. Assisted with siting and pre-design of injection and recovery facilities and served as the daily contact for EBMUD and the concerned water districts in California's Central Valley. [ALAMEDA COUNTY, CA]

Feasibility Study Implementation • Salinas Valley Reclaimed Water Injection and Recovery Program • Monterey Regional Water Pollution Control Agency
Implemented a feasibility study for reclaimed water injection/recovery (ASR) in the Salinas Valley. Developed a program for seasonally storing tertiary treated reclaimed water in the salt-water intruded portion of the Salinas Valley Aquifer. Coordinated meetings between local water agencies, city governments, the Water Pollution Control Agency, and regulatory agencies. [MONTEREY COUNTY, CA]

Geologic Assessment • Groundwater Assessment • Bear Valley | Fugro West
Conducted a geologic and hydrogeologic investigation showing that the existing wells were extracting groundwater in the most effective areas in the valley. A water budget was developed as part of the hydrogeologic investigation to estimate the amount of groundwater that could potentially be extracted from the valley. Additional wells were determined to be too expensive for the potential benefit. [ALPINE COUNTY, CA]

Hydrologic Modeling | Brackish Groundwater Development

Developed Flow Model • Saline Groundwater Intake and Disposal System Modeling and Design • City of Sand City
Developed a two-phase flow model of feedwater extraction and brine injection beneath the beach in Sand City for a planned desalination plant. The groundwater model was used to develop a unique arrangement of feedwater

wells and horizontal brine disposal wells that reduced environmental impacts on the National Marine Sanctuary. **[MONTEREY COUNTY, CA]**

Developed Flow and Transport Model • Desalination Brine Disposal Modeling • Marina Coast Water District
Developed a coupled density-dependent flow and transport model to help estimate and visualize the impacts from injecting brine from a small desalination plant beneath the sea floor. The model results suggested that the example brine discharge system created a subsurface brine mound that rose to the sea-floor surface, and entered the ocean at effectively full brine concentration. To obtain all the potential advantages of sea-floor injection, the injection system needed to inject brine over a larger area, at a lower injection rate. **[MONTEREY COUNTY, CA]**

Hydrologic Modeling | Recharge and Recovery

Developed Vadose Zone Model • Vadose Zone Modeling of Recharge with Reclaimed Water • Monterey County Regional Water Pollution Control Agency
Development of a vadose zone model for predicting travel times of water to the water table below a proposed recharge basin. The recharge basin was designed to infiltrate surplus reclaimed water from a regional wastewater treatment plant into a drinking water aquifer. The HYDRUS-2D model tested a series of likely hydraulic conductivity distributions based on field data to estimate a range of travel times. Model results showed that the testing program proposed for the recharge ponds would not result in the anticipated groundwater mounding. **[MONTEREY COUNTY, CA]**

Transport Model Development • Salinas Valley Reclaimed Water Injection and Recovery Program Modeling • Monterey Regional Water Pollution Control Agency
Employed a series of groundwater flow and contaminant transport models to study the effects of injecting reclaimed water into salt-water intruded aquifers beneath Salinas Valley. Used a local, variable density, contaminant transport model and a three-dimensional flow and transport model to demonstrate the impact of the injected reclaimed water on nearby water supply wells. **[MONTEREY COUNTY, CA]**

Hydrologic Modeling | Hydrologic Impact Study

Model Development • Avila Beach EIR Groundwater Model • Fugro West
Developed a flow and transport model of contamination beneath Avila Beach, California, where historical hydrocarbon contamination from leaking distribution pipes threatened the Pacific Ocean and the estuary of San Luis Creek. The groundwater model encompassed the entire town of Avila Beach, including the Pacific Ocean and San Luis Creek. Successfully demonstrated that significant impacts would result from proposed remediation. **[SAN LUIS OBISPO COUNTY, CA]**

Hydrologic Modeling | Contaminant Assessment & Remediation

Model Development • Groundwater TCE Plume Model • Scottsdale, Arizona
Retained as a neutral third party modeler for a TCE contaminated site with multiple potentially responsible parties. The model was used in negotiations with the USEPA to develop and implement remedial alternatives that ensure a

safe source of drinking water for the City, while preventing further degradation of the aquifers. [MARICOPA COUNTY, AZ]

WATER RESOURCES AGENCY

MEMORANDUM

Monterey County

DATE: March 4, 2019

TO: Gary Petersen, General Manager, SVBGSA
Leslie J. Girard, SVBGSA General Counsel

FROM: Howard Franklin, P.G.

SUBJECT: Opinion on Groundwater and Surface Water Interdependence in the Salinas Valley Groundwater Basin

As you know, I am currently employed as a Senior Hydrologist with the Monterey County Water Resources Agency ("Agency") and am a licensed professional geologist with the State of California. I have been employed by the Agency for over 23 years; a copy of my C.V. is enclosed. I also currently serve on the SVBGSA Advisory Committee, and am assisting in the development of the Salinas Valley Integrated Hydrologic Model (SVIHM) by the United States Geological Survey. The SVIHM will be utilized, in part, by the SVBGSA in preparing GSPs for the Salinas Valley Groundwater Basin ("Basin"). During my time with the Agency I have become familiar with the hydrology and hydrogeology of the Basin, and the relationship and interaction between groundwater and surface water in the Basin.

Regarding, the Salinas River within the Basin, the river does not meet the definition of a "subterranean stream, which is defined as groundwater that is flowing through known and definite channels." Although not a subterranean stream, the river is operated by the Agency with a specific objective of providing recharge to the Basin. Of an estimated 504,000 acre-feet per year of inflow to the Basin, approximately 50 percent occurs as stream recharge, most of which can be attributed to flows within the Salinas River channel. Surface water within the Salinas River channel is therefore a primary source of recharge to the Basin.

In much of the Basin, groundwater extraction and/or surface water diversions occurs from wells that are in direct communication with the shallow alluvial of the Salinas River channel. In these areas, it is difficult to differentiate between the extraction of groundwater and the diversion of surface waters. Additionally, as was experienced and monitored throughout the Basin during the most recent drought period, lowering of the groundwater table has a significant impact on the Agency's ability to operate the reservoirs to a controlled range of flows at the Salinas River Diversion Facility. As such, overdraft of the groundwater basin, resulting in a reduction in groundwater levels significantly impacted surface water flows, depleting the availability of surface water to riparian water users.

Groundwater and surface water users alike will benefit when projects designed to recharge the groundwater basin and provide water for fish passage, spawning and rearing, maintain groundwater levels. For this reason, within the Basin, groundwater and surface water can be regarded as an interdependent system.

Based on this interdependence, it is my opinion that both surface water and groundwater users in the Basin will benefit from projects operated to achieve a sustainable groundwater basin. It is also my opinion that the benefit received from a sustainable groundwater basin cannot easily be differentiated between the two user groups.

EDUCATION

MS University of Nevada, Reno, Hydrology/Hydrogeology August 1993
Thesis: "Applications of GIS Technology in Water Resource Investigations"
Advisor: John Warrick, PHD

BA Southern Illinois University, Carbondale, Biological Sciences May 1981
Minor: Geology
Minor: Geography (Cartography)
Minor: Microbiology

PROFESSIONAL QUALIFICATIONS

Manage and supervise professional geologist and engineers, scientist, technicians, general labor and administrative staff. Participate in strategic planning and budget development; Scope projects and develop budgets; Perform large scale and site specific scientific investigations; Oversee the development and implementation of complex basin wide integrated surface water groundwater models; Develop write and implement grant funded projects; Effectively planned and built heli-portable camps under extreme artic conditions.

Education, training and work experience in hydrology, hydrogeology, geology, geophysics, environmental science and water resource management. Licensed Professional Geologist in California (No. 8456).

Coordinated and implemented innovative projects in diverse environments; major metropolitan, agricultural, delta, desert, mountain and artic regions.

WORK EXPERIENCE

Monterey County Water Resources Agency, Salinas, California 1995 to present

- Hydrologist / Program Manager / Senior Water Resources Hydrologist

Reporting directly to the General Manager, plan, organize and manage the Hydrology section of the Monterey County Water Resources Agency; manage the most complex, innovative and large scale hydrogeologic investigations, projects and programs; prepare conceptual designs and investigations, manage detail design of project phases by other staff and engineers; conduct and guide subordinate supervisors in performance appraisals and employee counseling; select candidates for employment; prepare and manage program, project and section budgets; participate in the development of Agency wide budgets; represent the Agency at Board of Directors and County Board of Supervisor meetings; prepare grant applications; negotiate and administer contracts with vendors, agencies, and consultants; collaborate and coordinate with regulatory agencies; negotiate, prepare, review and administer agreements with other departments or public agencies; analyze proposed and current legislation and government policies, rules and regulations and develop strategic recommendations.

Parsons Engineering Science, Alameda, CA 1993 to 1995

- Hydrologist / Hydrogeologist

Performed hydrogeologic modeling, analysis, and report preparation of surface and ground water contamination sites. Developed geospatial database and performed analysis of major projects involving multiple sampling media. Utilized remote sensing technologies to locate and evaluate potential disposal sites on military instillations involving unexploded ordnance. Performed water resource evaluations, watershed characterizations, and geostatistical analysis projects.

Washoe County Department of Comprehensive Planning, Natural Resources Division, Reno, Nevada 1991 to 1993

- Graduate Intern

Developed, installed, and monitored a data collection network of rain gages, weirs, and weather stations for water resource evaluations. Performed streamflow measurements and snow pack surveys. Responsible for GIS data development and mapping.

Western Geophysical Company, International Division, Houston, Texas 1981 to 1991

- Exploration Manager

Managed the operation of geophysical exploration crews in extreme environments. Led projects in artic, coastal, delta, swamp, desert, mountain, agricultural, and urban regions. Supervised the coordination of air, aquatic, and terrestrial operations.

Global Marine Drilling, Inc, Homer, Louisiana Summers: 1978 and 1979

- Roustabout / Roughneck

Worked aboard the deep-sea exploration ship the Glomar Grand Isle performing duties in support of all drilling activities. Offshore Gulf Coast and South America.

Workshop and seminar on location and management of UXO detection and risk utilizing remote sensing technologies.

Groundwater-Surface Water Interaction: California's Legal and Scientific Disconnect - Symposium
Groundwater Resources Association of California, June 2011
Groundwater and surface-water are connected in the physical system, but not in the legal system, and the regulatory framework places pseudo boundaries to define under the influence. A debate has been heating up over the past few years as to whether the legal and regulatory system need to be changed to reflect physical reality and to protect the environment from further damage, whether local management initiatives and practice can effectively address the challenges, or some sort of hybrid needs to be developed for parts of the state. Our esteemed speakers and panelists will debate the pros and cons of the current system, and discuss their vision for California's future groundwater policy.

Principals of Groundwater and Flow Transport Modeling – Short Course
Groundwater Resources Association of California, September 2001
Principles and practical aspects of groundwater modeling.

PROTECTIVE ELEVATIONS TO CONTROL SEA WATER INTRUSION IN THE SALINAS VALLEY, CA

FIGURES

TABLES

APPENDIX

PROTECTIVE ELEVATIONS TO CONTROL SEA WATER INTRUSION IN THE SALINAS VALLEY, CA

1.0 BACKGROUND

This technical memorandum was prepared in support of preventing revocation of Permit 11043 (State of California Division of Water Rights Permit for Diversion and Use of Water - Amended Permit 11043 dated 11-Jul-49). Permit 11043 allows for appropriation of water from the Salinas River in Monterey County California, the quantity of which shall not exceed 400 cfs with an annual maximum diversion amount not to exceed 168,538 acre-ft/yr. Beneficial uses of the diverted water would add to and complement existing projects or implement new projects such as:

- Increase Ground Water Levels in the Pressure Area to Control Sea Water Intrusion
- Provide Additional Recharge to the Forebay And East Side Areas
- Provide More Water to the Salinas Valley Water Project
- Expansion of CSIP Deliveries
- Reduce Pumping in Pressure Area (in Lieu Recharge)

This report addresses one of the potential beneficial uses, that is, using the diverted water to help increase ground water levels in the Pressure and East Side Subareas to control seawater intrusion. The high quality diverted water would also result in improvement of ground water quality by blending with native ground water.

2.0 DESCRIPTION OF AQUIFER SYSTEMS

Water-bearing materials in the northern portion of the Salinas Valley, from oldest to youngest, consist of the Pliocene Marine Purisima Formation, Plio-Pleistocene Paso Robles Formation, Pleistocene Aromas Red Sands and the Holocene Valley Fill materials (Greene, 1970). In the Salinas Valley, according to Hanson et al. (2002), the upper portion of the aquifer system is present in the Holocene river and dune deposits, Valley Fill, Pleistocene Aromas Sands and the Paso Robles Formation. These water-bearing deposits consist of sand and gravel units which form aquifers in the upper 1,000 ft bgs[1] . Between 1,000 ft and 2,000 ft, the Pliocene Purisima Formation contains permeable sedimentary deposits which form a deeper aquifer system.

Aquifers in the Salinas Valley Ground Water Basin have been named for the average depth at which they occur. Beneath the center of the Salinas Valley within nine miles of the coast, the “180-Foot Aquifer” lies at an approximate depth of 50 to 250 ft, and has a thickness of 50 to 150 ft (Greene, 1970). The 180-Foot aquifer may correlate in part with the older valley-fill and upper Aromas Sands (Kennedy/Jenks Consultants, 2004; DWR, 1973; and Greene, 1970) and underlies a confining layer known as the Salinas Valley Aquitard (DWR, 2003; Hanson et al., 2002). The Salinas Valley Aquitard varies in thickness from 25 ft to more than 100 ft near Nashua Road, five miles west of Salinas (DWR, 1973; Montgomery Watson, 1994). Zones of discontinuous aquifers and aquitards approximately 10 to 200 ft thick underlie the 180-Foot aquifer (DWR, 1973). The “400-Foot Aquifer” lies at an approximate depth between 200 to 400 ft bgs, has a thickness of 230 to 350 ft, and may correlate with the lower Aromas Red Sands or Paso Robles Formation (Hanson et al., 2002; Greene, 1970). A deeper aquifer, also referred to as the “900-Foot Aquifer,” is separated from the overlying 400-Foot aquifer by a blue marine clay aquitard (DWR, 2003) and may be correlated with the Paso Robles Formations (Hanson et al., 2002). Figure 1 and Figure 2 depict the 180-Foot and 400-Foot aquifers. The 900-Foot aquifer is not shown on Figure 1 or Figure 2.

Existing published reports contain geohydrologic cross-sections of varying detail and applicability – such as those available in Greene (1970), DWR (1973), Harding ESE (2001), Hanson et al. (2002), and Kennedy/Jenks (2004). Cross-sections prepared by Kennedy/Jenks (2004) were used to help evaluate the extent of the base of the 180-Foot and 400-Foot aquifers and are discussed in a subsequent section of this memorandum (also see Appendix A).

[1] Below ground surface

3.0 PRESSURE AND EAST SIDE HYDROLOGIC SUBAREAS

Hydrologic subareas of the Salinas Valley have been delineated based on sources of ground water -recharge as well as stratigraphy. Historically, recharge to the Northern Salinas Valley comes primarily from two hydrologic subareas: underflow from the southern Forebay Subarea and underflow from the northeast East Side Subarea. The East Side Subarea is bounded by the Pressure Subarea on the west and Forebay Subarea on the south.

The East Side Subarea is recharged by streams draining the Gabilan Range to the northeast and from direct precipitation during wet years. The 180-Foot and 400-Foot aquifer zones in the Pressure Subarea are not found in the East Side Subarea. However, the East Side Shallow and Deep Aquifers can be time-stratigraphically correlated to equivalent zones in the Pressure Subarea (i.e. 180-Foot and 400-Foot aquifers). Therefore, the Pressure and East Side are in fact, hydrologically connected.

At one time (before excessive pumping), the East Side Subarea was one of the natural sources of recharge to the adjacent Pressure Subarea with ground water flowing from the northeast to the southwest. However, historical ground water level declines have resulted in a reversal of the gradient. That is, ground water now flows from the Pressure Subarea to the East Side Subarea (i.e. from the southwest to the northeast—see Figures 3 and 4).

4.0 HISTORICAL INTRUSION OF SEA WATER IN THE 180-FOOT AND 400-FOOT AQUIFERS

In general, ground water flows from areas of recharge to areas of discharge and the Salinas Valley is no exception. In the main Salinas Valley, ground water flows in a northwesterly direction from the inland recharge areas (Forebay Subarea) to the coast. Ground water also historically flowed from the East Side Subarea southwesterly into the Pressure Subarea. This natural flow of fresh ground water (towards the ocean) controlled inland migration of salt water into coastal aquifers. However, historical pumping has lowered ground water levels in both the 180-Foot and 400-Foot aquifer systems such that there is a landward hydraulic gradient which has caused extensive sea water intrusion (see Figures 3 and 4). It is believed that the primary mechanism of seawater intrusion is through the submarine outcrops of the 180-Foot and 400-Foot aquifers offshore of Monterey Bay. These outcrops are in direct hydraulic continuity with the Pressure Zone 180-Foot and 400-Foot aquifers. Graphical plots published by Monterey County Water Resources Agency (MCWRA, 2012) delineating historical extent of seawater intrusion, are shown on Figures 5 and 6 for the 180-Foot and 400-Foot aquifers respectfully. An analysis of these figures shows that the rate of seawater intrusion has progressively slowed due to implementation of the Salinas Valley Water Project and the Monterey County Recycling Projects. However, intrusion continues (albeit at a slower rate), migrating inland and salinating fresh-water aquifer systems. The following table summarizes the rate of seawater intrusion in the northern Salinas Valley as measured from the MCWRA plots (Figures 5 and 6).

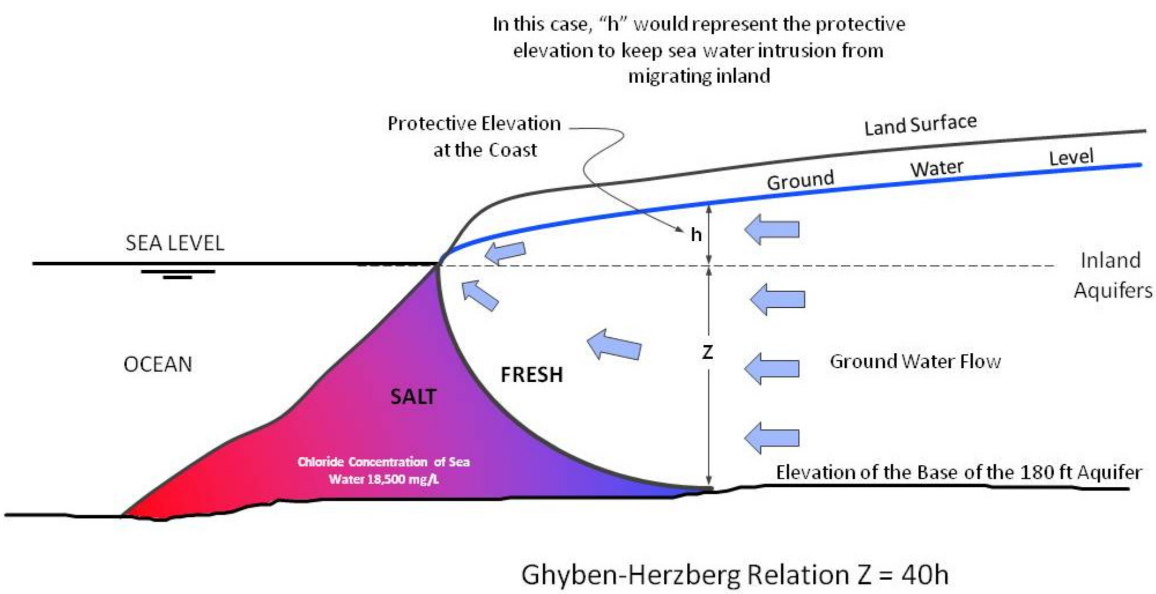
Table 1
Historical Rate of Sea Water Intrusion in the 180 and 400-Foot Aquifers, ft/yr

Time Interval	Aquifer	
	180-Foot	400-Foot
1944-1965	557	-
1959-1975	-	391
1965-1975	659	-
1975-1985	665	545
1985-1993	930	406
1993-1997	1028	1185
1997-1999	4086	1829
1999-2001	1418	1243
2001-2005	722	572
2005-2007	760	303
2007-2009	430	183
2009-2011	600	134

5.0 CONTROL OF SEA WATER INTRUSION – PROTECTIVE ELEVATIONS

Well over 100 years ago, two independent investigators Ghyben and Herzberg determined that salt water in aquifers was found at a depth below sea level of approximately 40 times the height of the fresh water above sea level (Todd, 1980). This distribution was due to the hydrostatic equilibrium between the densities of fresh water and seawater. The equation which explains this phenomenon is referred to as the Ghyben-Herzberg relation and assumes under hydrostatic conditions that the weight of a unit column of fresh water, extending from the ground water level to a point on the fresh/salt water interface, is balanced by a unit column of salt water extending from sea level to the same point on the interface. The figure below illustrates this principle.

Schematic Showing Protective Elevations and the Ghyben-Herzberg Relation



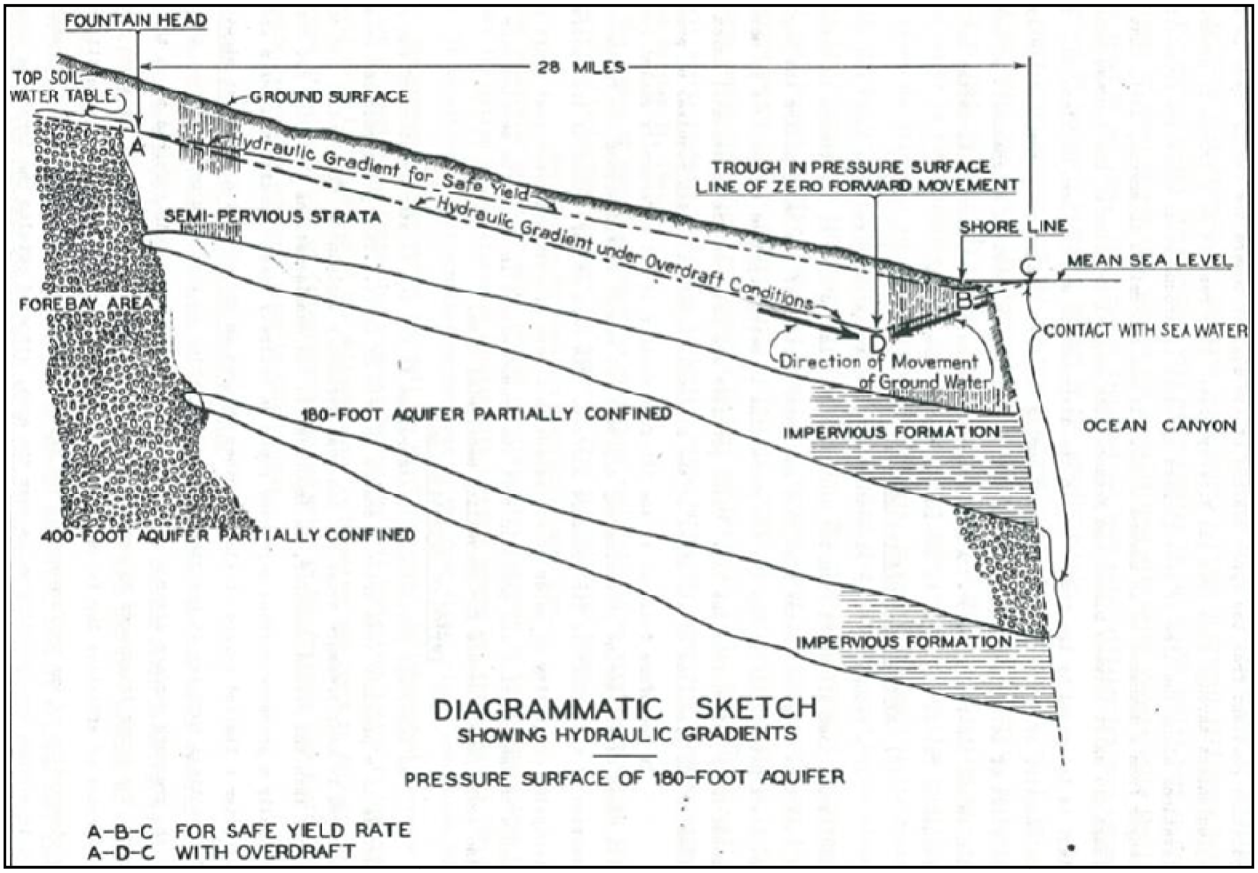
Protective elevations are defined as those ground water elevations which will keep the fresh/salt water interface from migrating inland. In the northern portion of Salinas Valley these elevations need to be above sea level and the flow of ground water towards the coast.

Ground water recharge (direct and in lieu), could be used to replenish storage and maintain a seaward hydraulic gradient. Additional recharge in the Forebay area would result in additional recharge to the northern pressure zone as underflow. Artificial recharge in the East Side Subarea would reduce subsurface inflow from the Pressure Subarea and eventually restore the historical northeast to southwest recharge. Both northwest underflow from the Forebay Subarea as well as southwest recharge from the East Side Subarea would help control seawater intrusion.

6.0 PROTECTIVE ELEVATIONS FOR THE 180-FOOT AND 400-FOOT AQUIFERS

One of the initial steps in the planning process for control of seawater intrusion is to quantify the protective elevations. As discussed above, in a simple hydrostatic case, protective elevations are defined as those ground water elevations (above sea level) which, due to density differences between fresh ground water and seawater, create a balance or equilibrium condition of the fresh water-salt water interface.

Schematic Showing Water Level Needed to Prevent Sea Water Intrusion (DWR, 1946)



The above sketch is from Plate 10 in DWR (1946) and shows the concept of establishing a seaward hydraulic gradient to prevent seawater intrusion. Near the coast it may be assumed that the chloride concentration is that of pure seawater (18,500 mg/L)[2] and the Ghyben-Herzberg 40:1 relation applies.

[2] http://shorestation.ucsd.edu/active/index_active.html

The extent of seawater intrusion varies in different aquifers due to a multitude of factors including aquifer depth, tidal influence, variation in hydrology and other water balance components. However, for planning purposes, the protective elevations as calculated in this technical memorandum are considered realistic for control of seawater intrusion. Protective elevations were calculated near the coast and merged with historical (1938) elevations obtained from Plates 8 and 9 (DWR, 1946).

Specifically, protective elevations for the 180-Foot and 400-Foot aquifers were calculated as follows:

1. The elevation of base of the 180-Foot and 400-Foot aquifers were obtained from recent geologic cross-sections and other publications (Figures 7, 8 and Appendix A).
2. The Ghyben-Herzberg relation of 40:1 was used to calculate the protective elevations at the Coast for each aquifer (see Figures 1 and 2).
3. Using the protective elevations at the coast and historical ground water flow directions as obtained from DWR Bulletin 52 (1946), the protective elevations were created assuming a seaward hydraulic gradient of 0.0002 (1 ft/mile) for both the 180-Foot and 400-Foot aquifers. This seaward hydraulic gradient is somewhat less than the historical gradient but as long as the coastal protective elevations are maintained by seaward flow, seawater intrusion can be controlled.

Figures 9 and 10 show the protective elevations and direction of ground water flow in the Northern Salinas Valley.

7.0 HISTORICAL DEPLETION OF STORAGE IN A PORTION OF THE 180-FOOT AND 400-FOOT AQUIFERS

The ground water storage depletion between the protective elevations (Figures 9 and 10) and current ground water elevations (Figures 3 and 4) was made for a portion of the 180-Foot and 400-Foot aquifers between the town of Salinas and the Coast. Historical ground water storage depletion was estimated by multiplying the historical change in hydraulic head by the area and aquifer storativity. For example, for the 180-Foot aquifer, the current ground water elevations (Figure 3) were subtracted from the protective elevations (Figure 9). This difference was then multiplied by the 180-Foot aquifer area and the storativity. Similarly, for the 400 Foot aquifer, the depletion in storage was calculated by subtracting current water levels (Figure 4) from protective elevations (Figure 10) and multiplying by the area and the 400-Foot aquifer storativity. Incremental areas and storativity values for each aquifer were obtained from the SVIGSM[3] model cells.

Keep in mind that since these aquifers are confined and semi-confined, the change in ground water storage is relatively small and is due to the compression of the aquifer and expansion of the water. This volume is several orders of magnitude lower than the water which would drain by gravity (from aquifer pore space) in an unconfined state. Table 2 summarizes historical change in ground water storage.

Table 2
Historical Depletion of Storage in a Portion of the 180-Foot and 400-Foot Aquifers Between the Town of Salinas and the Coast

Aquifer	Area Between the Coast and Salinas, acres	Average Decline of Water Level ft	Aquifer Storativity	Volume of Storage Depleted acre-ft
180-Foot	84,000	33	0.004	11,100
400-Foot	84,000	51	0.00009	400
			TOTAL	11,500

[3] Salinas Valley Integrated Ground Water-Surface Water Model

8.0 FLOW NEEDED TO MAINTAIN A SEAWARD HYDRAULIC GRADIENT

Table 2 (above) shows that a relatively small amount of water is necessary to replenish confined and semi-confined aquifer storage. More important in controlling seawater intrusion however, is the re-establishment of the coastal protective elevations and seaward hydraulic gradients. It is estimated that between 1970 and 1992 approximately 16,000 acre-ft/yr of intrusion occurred in the 180-Foot and 400-Foot aquifers (Montgomery Watson, 1994).

The amount, location and timing of ground water recharge (direct and in lieu), needed to maintain protective elevations and a seaward hydraulic gradient was determined using the SVIGSM. Based on model results, and assuming 2030 land use conditions, 12,000 acre-ft/yr will be required from the SVWP Phase I facilities and 48,000 acre-ft/yr will be required from the SVWP Phase II facilities. Given the hydrologic variability in the Salinas Valley area, in order to supply a total of 60,000 acre-ft/yr (on average), to the SVWP, it will be necessary to have the right to divert up to 135,000 acre-ft/yr from the Salinas River.

HYDROGEOLOGY AND WATER SUPPLY

OF SALINAS VALLEY

A White Paper prepared by

Salinas Valley Ground Water Basin
Hydrology Conference

For
Monterey County Water Resources Agency

June 1995

TABLE OF CONTENTS

CONCLUSIONS

- No member of this panel has any substantive disagreement with the conclusions of previous reports.
- The panel reached unanimous agreement on all major issues.
- Data that are available have been useful in determining regional and local surface water and ground water relationships and quality.
- Based on all the studies completed to date, there appears to be an adequate supply of water within Salinas Valley to meet all existing and projected future requirements.
- Despite this abundance, past and present water distribution and management practices have caused seawater intrusion, declining ground water levels in the East Side Area, and nitrate contamination.
- The solution for the seawater intrusion and declining ground water levels in Salinas Valley that was recommended in 1946 is so compelling we could not refrain from recommending it.
- Some form of extraction and conveyance system should be constructed.
- More recent studies conducted by Monterey County Water Resources Agency (MCWRA) since 1946 have reaffirmed and endorsed the original concepts.
- Residents of Salinas Valley are fortunate that an in-valley conjunctive use solution is available to them.

RECOMMENDATIONS

Monterey County Water Resources Agency should:

- Complete the extraction facilities and conveyance system, similar to those that were outlined in California Department of Water Resources Bulletin 52 in 1946, that are integral components of a total project.

- Continue studies to determine the relationships between fertilizer application, irrigation practices, plant growth, movement of water past the root zone, and ground water contamination under growing conditions prevalent in Salinas Valley.

- Use these studies to develop and demonstrate improved irrigation and fertilizer management methods that farmers can adopt with confidence.

- Continue to evaluate seawater intrusion monitoring data.

- MCWRA should continue their surface water and ground water monitoring program for quantity and quality. The data should be evaluated to ensure that the information is adequate for effective management of water resources.

INTRODUCTION

Purpose and Scope

The Monterey County Water Resources Agency (MCWRA) convened a panel of 10 geologists, hydrogeologists, and engineers familiar with Salinas Valley ground water basin to attempt to reach agreement on the basic physical characteristics of the basin, and the surface and ground water flow within the basin. Agreement on the completeness and accuracy of existing data and previous hydrogeological studies was seen as an important first step in identifying and implementing a technically sound solution acceptable to the public that would stop seawater intrusion that began some 60 years ago.

Mike Armstrong, General Manager of MCWRA, instructed the panel to review and, if possible, reach consensus on the hydrogeological characteristics of the basin, define clearly the water resources problems in the basin, and determine surface water and ground water flow within the basin. We were not requested to discuss specific local projects or political and institutional aspects of the problems.

The panel met in a closed-door session in Monterey on May 24 and 25, 1995. The session was closed to the public and the press to enable the panelists to discuss and explore ideas and opinions freely without worrying about statements, questions, and hypotheses being repeated out of context.

Members of the panel believe the process worked very well. This report presents our findings, conclusions, and recommendations. We were able to achieve more than our original scope of work. There was remarkable unanimity of opinion on our understanding of the physical characteristics of the basin, the hydrologic system, the interaction between surface water and ground water, and definition of the specific ground water problems in the basin.

In summary, the facts we agreed upon point so compellingly toward an already identified *regional* solution to the Valley's ground water resources problems that the panel has included a potential solution. We have included a strong recommendation in this White Paper for implementing that regional solution.

Panel Members

The panel consisted of 9 members and 1 facilitator/editor:

Mr. Carl Hauge, California Department of Water Resources, Sacramento, facilitator/editor.

Dr. Steven Bachman, Integrated Water Technologies, Santa Barbara.

Mr. Tim Durbin, HCI Hydrologic Consultants, Davis.

Mr. Martin Feeney, Fugro West, Monterey.

Mr. Joseph Scalmanini, Luhdorff and Scalmanini, Woodland.

Mr. Jim Schaaf, Schaaf & Wheeler, San Jose (attended May 25 only).

Dr. Dennis Williams, GEOSCIENCE, Claremont.

Mr. Gus Yates, Jones & Stokes Associates, Sacramento.

Dr. Young Yoon, Montgomery Watson, Sacramento.

Mr. Matt Zidar, Monterey County Water Resources Agency, Salinas.

Previous Reports

One of the first reports published on the hydrology of Salinas Valley was California Department of Water Resources Bulletin 52, *Salinas Basin Investigation,* released in 1946. Bulletin 52 recommended construction of a project consisting of dams to provide additional recharge and yield throughout the Valley, ground water extraction facilities, and a water conveyance facility to transport some of the additional yield to the area near the coast.

Other recent reports include:

Durbin, T.J. Kapple, G.W., and Freckleton, J.R., 1978, *Two-dimensional and three-dimensional digital flow models of the Salinas Valley ground water basin, California*; U.S. Geological Survey Water-Resources Investigation 78-113, 134 p.

Leedshill-Herkenhoff, Inc., 1985, *Salinas Valley Seawater Intrusion Study.*

Montgomery Watson, 1994, *Salinas River Basin Water Resources Management Plan, Task 1.09 SalinasValley Groundwater Flow and Quality Model Report.*

Todd, D.K., Consulting Engineers, Inc., 1989, *Sources of Saline Intrusion in the 400-Foot Aquifer, Castroville Area, California.*

Yates, E.B., 1988, *Simulated Effects of Ground-Water Management Alternatives for the Salinas Valley, California,* United States Geological Survey Water Resources Investigation Report 87-4066.

PROBLEM STATEMENT

The water resources problem in Salinas Valley is not a water supply problem. It is a water distribution problem. The basin has enough surface and ground water to meet existing and projected future average annual agricultural, and municipal and industrial (M & I) water demand through the year 2030. The problem lies in managing those supplies to meet water demands at all locations in the Valley at all times.

The overall water resources problem has three principal components:

- Seawater intrusion

  Seawater intrusion occurs near the coast principally because extraction of fresh ground water in the northern part of Salinas Valley exceeds recharge in the northern part of the Valley.

  In recent decades, the annual volume of intrusion has ranged from 2,000 to 30,000 acre feet per year (afy) and has averaged 17,000 acre feet per year.

  Seawater has advanced about 6 miles inland.

  About 20,000 acres of agricultural land near the coast are underlain by one or more aquifers that contain water too salty to use for irrigation.

- Declining ground water levels in the East Side Area

  Ground water levels continue to decline in the East Side Area.

  Lower ground water levels in the East Side Area induce additional recharge from the Pressure Area and the Forebay Area but also cause conditions for potential movement of additional seawater inland into the coastal area.

- Nitrate contamination

  Nitrate has contaminated ground water to varying concentrations throughout the Valley, but the level of contamination is especially high in the East Side, Forebay, and Upper Valley Areas.

  The maximum contaminant level (MCL) for drinking water is 45 mg/l as nitrate. In 50 percent of the wells sampled throughout the Valley, nitrate exceeds 45 mg/l; in some wells nitrate has reached several hundred mg/l.

High concentrations of nitrate limit beneficial use of the ground water for potable uses and for some agricultural uses.

An additional long-range problem is the build up of salts in the basin that is occurring because there is no subsurface outflow from the basin. Although the impacts of such a condition are manifested much more slowly than other problems, there is a long-term increase in salt concentration within the aquifer system. At some time in the future, such a build up will render the aquifer system unusable for certain beneficial uses.

These water resources problems result in economic and institutional consequences primarily because of water quality standards and the loss of supply associated with violation of those standards. The severity of the economic and institutional problems is not the same for all 3 of the problems and is dependent on the specific location and the use of the water.

The variability of precipitation and runoff is an important component of water supply planning and management. Water supply issues may appear to be non-existent when the *average* annual water supply is used for planning purposes. But in dry years, which are also a part of that average, those same supply issues become critical.

DESCRIPTION OF THE BASIN

Hydrogeology

The Salinas Valley ground water basin is one hydrologic unit. Four subareas based on differences in local hydrogeology and recharge have been identified: Upper Valley Area, Forebay Area, East Side Area and Pressure Area (which includes the area near the coast). All information collected to date indicates there are no barriers to the horizontal flow between these subareas, although aquifer characteristics decrease the rate of ground water flow in certain parts of the basin (for example, from the Pressure Area to the East Side Area, and especially from the Forebay Area to the Pressure Area). Ground water can move between the East Side and Pressure Areas, and between the Forebay and Pressure Areas, the Forebay and East Side Areas, and the Upper Valley and Forebay Areas. The "boundaries" between these areas have been identified as zones of transition between different depositional environments in past millennia.

While Salinas Valley ground water basin is one hydrologic unit, the impacts of ground water use are not distributed uniformly throughout the Valley. The impacts of ground water extraction occur mostly within the local area of the extraction. The impacts diminish rapidly with distance from the extraction, and the impacts tend to be very small at large distances from the extraction.

The alluvial fill in Salinas Ground Water Basin encompasses approximately 344,000 acres. The Upper Valley and Forebay Areas are unconfined and in direct hydraulic connection with Salinas River. The Upper Valley Area covers an area of approximately 92,000 acres near the south end of Salinas Valley from Greenfield to Bradley. Primary ground water recharge to the Upper Valley Area occurs from percolation in the channel of Salinas River.

The Forebay Area from Gonzales to Greenfield, consists of approximately 87,000 acres (including Arroyo Seco Cone) of unconsolidated alluvium. Principal recharge to the Forebay Area is from percolation of water from Salinas River and Arroyo Seco Cone, and ground water outflow from the Upper Valley.

Arroyo Seco Cone is located on the west side of southern Salinas Valley and is a part of the Forebay Area. Arroyo Seco Cone receives recharge from percolation in channels of Arroyo Seco and tributaries. The Cone covers approximately 26,000 acres of the Forebay Areas. The Arroyo Seco Cone may provide some opportunity for additional recharge.

The Pressure Area covers an area of approximately 91,000 acres between Gonzales and Monterey Bay. The Pressure Area is composed primarily of confined and semi-confined aquifers separated by clay layers (aquitards) that limit the amount of vertical recharge. Three primary water bearing strata have been identified in the Pressure Zone: the 180 Foot Aquifer, the 400 Foot Aquifer, and the Deep Zone. These aquifers are separated by aquitards, although some vertical recharge occurs locally where the aquitards are thin or missing. The uppermost aquitards allow some limited recharge from Salinas River directly to the 180-foot aquifer in the area near Spreckels. The areas of thin or missing aquitards also allow some interconnection between the shallow (180 foot) and deeper (400 foot) aquifers.

The exact nature of the connection between the Deep Zone and the ocean is unknown. Seawater intrusion has not been detected in Deep Zone wells, but there is no evidence indicating that the Deep Zone is not connected to the ocean. Lacking this evidence, it must be assumed that the deep zone, like the 180-foot and 400-foot aquifers above it, is connected to the ocean and vulnerable to seawater intrusion if ground water levels fall below sea level. Similarly, the aquitards between the 400-foot and the Deep Zone are subject to leakage of degraded water downward to the Deep Zone as the water level is lowered.

The Deep Zone is currently undefined both geologically and areally. In some locations, it is considered to be Purisima Formation, in others, lower Paso Robles Formation. Some recent evidence suggests that it may be Santa Margarita Formation. Water levels in Deep Zone wells have fallen approximately 60 feet since the late 1970s and are now substantially below sea level. Total extraction over this period of time has averaged less than 5,000 acre-feet per year. Water quality in the Deep Zone is unsuitable for agriculture because of extremely high sodium-adsorption ratios (SAR).

The East Side Area consists of 74,000 acres and contains unconfined and semiconfined aquifers in the northern portion of the Basin that historically received recharge from percolation from stream channels on the west slope of the Gabilan Range. As a result of extraction in excess of recharge, the decline in ground water level in the East Side Area has induced subsurface recharge from the Pressure Area, as well as from Salinas River and the Forebay Area. This inflow is now a larger source of recharge than the stream channels coming from the Gabilan Range.

Sources of Recharge

Ground water recharge in Salinas Valley is principally from infiltration from Salinas River, Arroyo Seco Cone, and, to a much lesser extent, from deep percolation of rainfall. Minor amounts are derived from infiltration from small streams and inflow from bedrock areas adjoining the basin. Deep percolation of applied irrigation water is the second largest component of the ground water budget, but because it represents recirculation of existing ground water rather than an inflow of "new" water, it is not considered a source of recharge for this discussion. Seawater intrusion is another source of inflow to the basin, but because it is not usable fresh water it is also excluded as a source of recharge for this discussion.

Infiltration from Salinas River and deep percolation of rainfall would occur under natural conditions, but both are increased by present water use patterns in the Valley. Ground water extraction increases the amount of infiltration from the river upstream of Salinas. Irrigation increases the amount of rainfall that percolates past the root zone by increasing antecedent soil moisture at the beginning of the rainy season. The low permeability of the Salinas Valley aquitard in the Pressure Area decreases but does not altogether eliminate deep percolation of rainfall and irrigation return flow directly to the 180-foot aquifer in the Pressure Area.

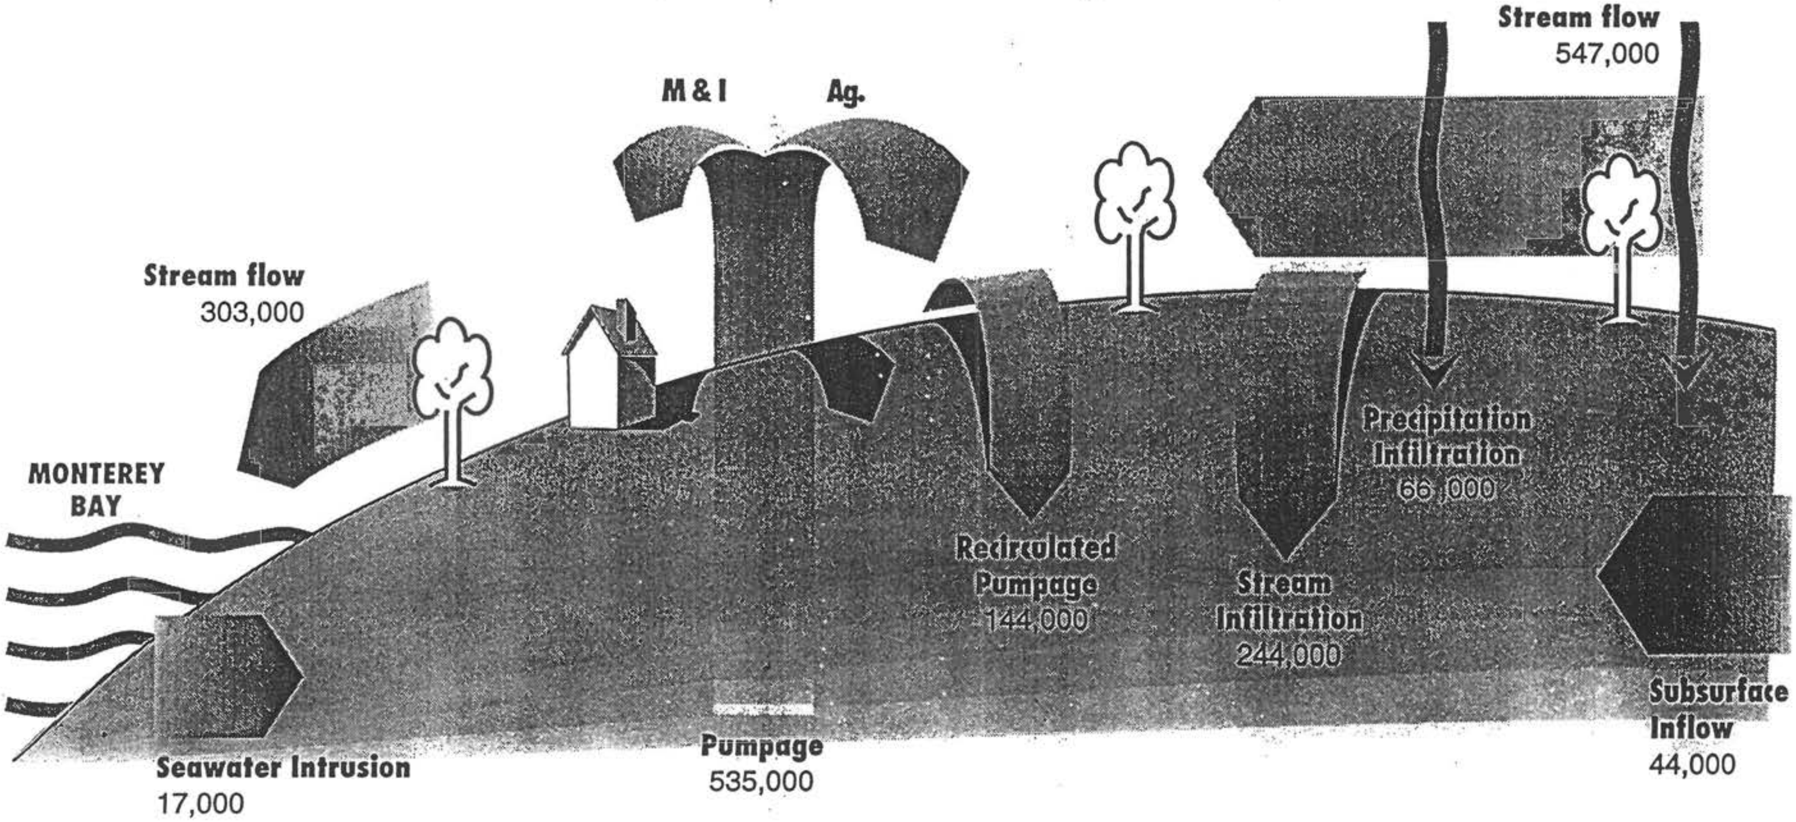
Figure 1 shows estimates of the average annual amounts of recharge derived from each source during 1970-1992 for the entire Valley. Average annual recharge, including irrigation return flow and seawater intrusion, totals 514,000 afy.

The estimates of items in the water budget are derived from a combination of direct measurement and extrapolation using three different and independently designed ground water models. It is important to recognize that the models include all available measured data and that all three of the modeling efforts completed to date have resulted in very similar estimates of the average annual basin-wide water budget. Our confidence in the general magnitude and proportion of flows in the budget is fairly high.

The water budget shown in Figure 1 is an average annual budget indicative of the long-term balance of components of the budget. It does not reveal the large amount of variation in annual flows in the water budget. These annual variations are an important factor in management of water resources and must be considered in any solution to water management in Salinas Valley.

The water budget indicates that ground water storage in the Valley has declined by 460,000 acre feet from 1970 to 1992, an average rate of 20,000 afy. However this decline was

Average Annual Basin-Wide Surface and Ground-Water Flows in Salinas Valley (AFY, 1970-1992 average flows)



Change in Ground Water Storage = -20,000 AFY

caused largely by the 1987 through 1992 drought.

Infiltration of water from Salinas River is relatively constant from year to year, partly because river flows are partially regulated by Nacimiento and San Antonio reservoirs and partly because ground water extraction--which induces a substantial amount of infiltration from the river--also remains fairly constant. In contrast, rainfall recharge is much more variable, with little, if any, recharge occurring in below-average rainfall years and large amounts occurring in wet years.

In the Upper Valley and Forebay Areas recharge from Salinas River is a rapid process, so that the effects of dry years on ground water levels are rapidly reversed in subsequent normal and wet years. After declining somewhat during the 1976-1977 and 1986-1992 droughts, water levels in the Upper Valley and Forebay Areas recovered fully within 1 to 2 years following the resumption of normal streamflow, including reservoir releases. This demonstrates the feasibility of conjunctively using ground water storage capacity in those areas to increase overall system yield.

BASIN MANAGEMENT

Seawater Intrusion

Analysis of water samples from wells in the Pressure Area has indicated that seawater has been intruding the aquifers for the last 60 or so years. The intrusion has moved progressively landward within the 180-foot and 400-foot aquifers during this time. To date, there has been no observed intrusion in the Deep Zone. The intrusion has moved as much as 6 miles inland in the 180-foot aquifer and 2 miles inland in the 400-foot aquifer, rendering wells in the intruded area unusable and decreasing usable basin storage. Between 1970 and 1992, the annual decrease in usable basin storage for ground water because of seawater intrusion has amounted to an average of 17,000 acre feet per year. While the average is 17,000 acre feet per year, it has varied from 2,000 acre feet per year to 30,000 acre feet per year. The cumulative total of seawater intrusion during the period 1970 to 1992 is about 374,000 acre feet.

Seawater intrudes coastal aquifers when ground water levels in the aquifers in contact with seawater decline below sea level. When this occurs, the normal gradient that produces ground water discharge into Monterey Bay is reversed. This reversal of ground water gradient in the Pressure Area resulted from extraction of ground water in excess of recharge in that Area. Seawater has intruded the aquifer in response to the reversed gradient that was caused by lowered ground water levels.

This saline water can move both horizontally within the aquifer or vertically through breaches in the various aquitards or through improperly constructed wells, wells that were abandoned but not destroyed, or through failed well casings. Most of the salinity is caused by intrusion of seawater through the offshore outcrops of the aquifers. An additional source of salinity may be the dewatering of salty marine clays within or between the aquifers in response to the lowered pressure levels in the aquifer system.

If the intrusion of seawater is left unchecked, seawater will continue to advance inland, eventually contaminating the East Side and Pressure Areas as far inland as Salinas. This will degrade the water supply of additional agricultural areas and will also degrade municipal drinking water supplies.

The only effective solution to controlling seawater intrusion in Salinas Basin is the re-establishment of higher ground water levels by relieving pumping stresses in the coastal portion of the aquifer. This can most efficiently be achieved by the cessation of pumping and the delivery of an alternative source of water to this area. This solution will allow recovery of water levels in the aquifer, thereby halting the advance of seawater intrusion and restoring normal aquifer pressures. The re-establishment of these conditions will also control the other possible sources of saline degradation such as the dewatering of marine clays and interaquifer leakage.

If a solution other than the delivery of water to the coastal area is to be considered, additional information regarding the components of the saline intrusion may be advisable.

Overdraft

In general, the term overdraft has been used to describe conditions where extraction from a ground water basin exceeds the perennial yield over a period of time, resulting in undesirable conditions. Undesirable conditions may include subsidence, seawater or other saline water intrusion, lower ground water level, and depletion of the supply. Perennial yield is sometimes called the safe yield or the sustained yield of the basin.

In Salinas Valley, the undesirable conditions lowered ground water levels and seawater intrusion. The conditions are the result of:

a) the physical characteristics of ground water occurrence in the Valley,

b) physical connection between the aquifers and seawater,

c) areal distribution of extraction from the aquifer system, and

d) water use practices.

These conditions require that management of ground water in different parts of the Valley recognize local hydrogeologic issues specific to each area.

There is a difference between total ground water in storage and usable ground water storage. The **total** storage of ground water in Salinas Valley is in the millions of acre feet. The **usable** storage is only a portion of the total volume in storage because all of the ground water is not available for extraction without causing some of the undesirable impacts that were listed above. Usable storage can be greatly influenced by the distribution of extraction and recharge facilities, water management practices, and physical facilities for storage and distribution of surface water and ground water.

Valley-wide, the ground water basin is only slightly out of balance because total inflow to the aquifer system is less than total outflow. Fresh water inflow consists of recharge from precipitation, streamflow, and recirculated irrigation water. Outflow consists of ground water extraction, which totals 20,000 afy more than total fresh water inflow.

Seawater is another source of inflow because of the lowering of ground water levels near the coast. The high chloride content, however, makes this water unusable. The average seawater intrusion totals about 17,000 afy. Thus, the Valley-wide water budget shows an average fresh water deficit of 37,000 afy.

In addition to the overdraft in the East Side Area and seawater intrusion in the Pressure Area, 2 other factors exacerbate the ground water supply problem in the Valley. First, nitrate concentrations in ground water are increasing in many areas of the Valley. Second, the basin is hydraulically closed to subsurface outflow, leading to long-term salt accumulation.

The undesirable conditions in the Valley include: seawater intrusion near the coast, decreasing ground water in storage in the East Side Area, nitrate increases in the Forebay and Upper Valley Area, and the salt build-up caused because the Valley is hydraulically closed. These conditions are occurring despite the fact that an essentially full aquifer system has existed under the major portion of the Valley.

The solution to these problems lies in focused relief of the pumping stresses. Such relief could include reduced local extraction in the areas where intrusion and declining water levels are occurring, development of a supplemental water supply to replace the reduced extraction, while maintaining current beneficial uses.

Nitrate

Nitrate contamination of ground water poses a significant threat to the beneficial use of ground water for drinking water and for some agricultural water uses. Nitrate concentrations exceed drinking water standards in many parts of the basin. The principal source of nitrates to ground water is almost certainly excess fertilizer that is leached by rainfall and applied irrigation water. Nitrates also originate from animal and human waste. The contribution of nitrate from various sources has been estimated at 90 percent from agriculture and 10 percent from urban sources. Contamination by nitrate has been observed in the unconfined aquifer and in some locations in the 180-foot aquifer of the Pressure Area.

Nitrate contamination can best be controlled by integrated on-farm fertilizer and water management practices. Such practices may require the voluntary implementation of improved water and fertilizer management by growers, possibly with incentives from MCWRA.

Water Conservation

There are probably some water supply benefits that can be achieved by implementing agricultural and urban water conservation measures. In agriculture, the potential savings would be achieved by decreasing direct evaporative losses during irrigation and by minimizing outflow of irrigation return flow from coastal areas to Monterey Bay. The potential for agricultural conservation of irrigation water is closely linked with interactions in the plant root zone, crop yield, and salt build-up. Any attempt to improve irrigation efficiency must evaluate each of these factors.

Water conservation by itself would not be sufficient to solve the problems of seawater intrusion near the coast and overdraft in the East Side Area.

PROBLEM SOLUTION

Seawater Intrusion and Overdraft

The only reasonable and effective solution for controlling seawater intrusion and overdraft in Salinas Valley is re-establishment of higher ground water levels by relieving pumping stresses in the aquifers in the Pressure and East Side Areas. The 2 alternatives for relieving pumping stresses are either 1) fallow land in the Pressure and East Side Areas, or 2) deliver an alternate supply of water to replace the reduced pumpage. If present agricultural and urban beneficial uses of water are to continue, the obvious solution is some sort of program to deliver water in lieu of ground water extraction. The Castroville Seawater Intrusion Project is a step in this direction, but it will not provide enough water to replace current extraction sufficiently to halt seawater intrusion.

Two approaches could be used to relieve overdraft in the East Side Area. One approach would be to allow water levels to continue declining. They would eventually stabilize near a level low enough to induce increased inflow from the Forebay and Pressure Areas at a rate sufficient to balance ground water extractions. This approach would result in high ground water extraction costs for the indefinite future and continued seawater intrusion in the Pressure Area.

An alternative approach would be to deliver in-lieu water to the East Side Area by means of a surface conveyance facility. This approach would decrease local ground water extraction costs and avoid the intrusion risk but would incur construction and pumping costs for the surface water facility.

The water-supply problem in Salinas Valley is the result of a water distribution problem. The water supply in Salinas Valley is the streamflow runoff from Salinas River watershed and the deep infiltration of precipitation on the Salinas Valley floor. However, a substantial part of this water supply is not captured at present and discharges to Monterey Bay from Salinas River. This discharge occurs mostly during storm periods, and the largest part of the discharge occurs during extreme flood events. The water-management solution to stop overdraft consists of facilities and management practices that use part of the discharge to Monterey Bay from Salinas River, while providing protection for instream uses in the River and in wetlands.

Valley-wide water management in Salinas Valley could best be accomplished by the conjunctive use of surface water and ground water storage. Storage could be used to retain some storm runoff from Salinas Valley watershed and the stored water could be made available for beneficial use within Salinas Valley. At present, runoff is stored in San Antonio and Nacimiento Reservoirs and within the ground water basin, but the current use of ground water storage is not adequate to resolve the problems of seawater intrusion into the Pressure Area and water-level declines within the East Side Area. More intensive management is required to address such conjunctive operation of surface water and ground water storage.

The need for conjunctive operation of surface water and ground water storage was recognized as early as 1946. In 1946, the California Department of Water Resources published a report on Salinas Valley that described the occurrence of seawater intrusion and declining ground water levels. The report recommended a project to eliminate these problems that included development of surface water and ground water storage. Surface water storage was to be accomplished by the construction of dams on tributaries to Salinas River, and ground water storage was to be accomplished by ground water transfers from the Forebay Area to the Pressure Area and East side Area. The Department recommended transfer facilities that included wells in the Forebay Area, conveyance facilities from the Forebay Area to the Pressure and East Side Areas, and distribution facilities within the Pressure and East Side Areas.

In such a conjunctive operation, the increased extraction in the Forebay Area and conveyance of water to the Pressure and East Side Areas would vacate ground water storage in the Forebay Area. This empty storage space would be refilled by additional infiltration from Salinas River. This mode of operation would effectively capture some of the water that presently flows to the ocean and would make it available for conveyance to the Pressure and East Side areas. The well-documented rapid recovery of ground water levels in the Forebay and Upper Valley Areas following recent drought years demonstrates the physical feasibility of this type of conjunctive use.

Part of the recommended facilities for surface water and ground water storage have been completed by the construction of the dams for SanAntonio and Nacimiento reservoirs, but the facilities for the effective use of ground water storage have not been completed. The operation of San Antonio and Nacimiento reservoirs has produced benefits to salinas Valley, but the ultimate benefits that would result from the construction and operation of transfer facilities have not been realized.

The panel concluded that the facilities recommended in 1946 by the California Department of Water Resources should be completed immediately. The Department recommended both dams and transfer facilities. Since that time, additional studies conducted by MCWRA have served to reaffirm and validate the original recommendations.

The dams that were recommended have been constructed, but the companion transfer facilities have not been constructed. The result of partially completing the project has been an uneven distribution of benefits throughout the Valley. The Forebay Area and Upper Valley Areas have enjoyed relatively large benefits from San Antonio and Nacimiento reservoirs that would have been shared equally with the Pressure and East Side Areas if the intended transfer facilities had been built. In the absence of the transfer facilities, seawater intrusion into the Pressure Area and water-level declines within the East Side Area have not been mitigated.

Instead, within the Forebay Area ground water levels are 20 to 30 feet higher than would have occurred without the dams. The Upper Valley Area has also benefited from somewhat higher ground water levels, and has used the yield of the 2 reservoirs to significantly increase the amount of irrigated land in this Area. Benefits have accrued also to the Pressure Area where seawater intrusion is 30 percent less than would have occurred. Benefits to the Pressure and East Side Areas have been relatively small

When Nacimiento and San Antonio dams were built, the effect of the additional water on seawater intrusion could not be predicted, and a "wait and see" attitude was adopted. Since the 2 dams have been operating, it has become clear that the Forebay Area has benefitted from essentially "full" ground water storage, but the ground water flow into the Pressure and East Side Areas has not been sufficient to stop the seawater intrusion and overdraft in these 2 areas. The remaining components of the solution proposed originally, an overland transfer of water directly to the intruded and overdrafted areas, are necessary to solve those problems.

The California Department of Water Resources recommended an effective plan for water-supply management within the Salinas Valley. That plan has been partly implemented. We recommend in the strongest terms that the transfer component be implemented immediately. Transfer of ground water from the Forebay Area to the Pressure and East Side Areas is the only feasible approach to eliminating seawater intrusion into the Pressure Area and water-level declines within the East Side Area. As recommended by the Department and others, transfers would be accomplished by extraction within the Forebay Area, conveyance of the extracted ground water to the Pressure Area, and distribution of water within the Pressure and East Side Areas.

The transfer facilities would produce minor water level declines within the Forebay Area. However, studies estimate that the solution can be accomplished by limiting the average decline to about 5 feet, and maximum localized decline to about 20 feet. The Forebay Area has enjoyed an average water-level rise of 25 feet due to operation of San Antonio and Nacimiento reservoirs. With transfer facilities, the average annual water-level rise, relative to pre-project conditions within the Forebay Area, would still be about 20 feet, seawater intrusion into the Pressure Area would be eliminated or severely curtailed, and water-level declines would be stopped within the East Side Area. With transfers, benefits would be distributed more uniformly throughout the Valley. Without transfers, the benefits would continue to be weighted toward the Forebay and Upper Valley Areas.

Nitrate

MCWRA knows enough about the nitrate problem to recommend initial steps to manage it. However, additional study is needed to understand the complex interrelationships of crop, irrigation, fertilizer, and soil management under conditions prevalent in Salinas Valley. Additional research into the plant-water-soil-nutrient relationships on specific soils in Salinas Valley will be required to maintain an acceptable salt balance and acceptable crop yields.

Critical information is not available to encourage growers to adopt best management practices for the mitigation of nitrate contamination of ground water. An intensive program must be undertaken by MCWRA to provide information on the effectiveness of practices for the management of soils for water conservation and the mitigation of nitrate contamination. Information is available to make initial steps toward developing best management practices, but additional information is critical to the long-term success of improved soils management.

Water Conservation

Some water supply benefits can probably be achieved by implementing agricultural and urban water conservation measures. In agriculture, the potential savings would be achieved by decreasing direct evaporative loss during irrigation and minimizing outflow of irrigation return flow from coastal areas to Monterey Bay, while maintaining a favorable salt balance.

On-farm management of irrigation needs to be done jointly with management of fertilizer application and salt leaching requirements. We recommend that MCWRA undertake studies to further understand these interrelated issues and develop best management practices tailored to growing conditions in Salinas Valley.

However, water conservation by itself would not be sufficient to solve the problems of seawater intrusion near the coast and overdraft in the East Side Area.

LAST WORD

The solution to the water resource problems within the Salinas Valley has been known since at least 1946. The solution that was proposed then by the California Department of Water Resources recognized that sufficient supplemental water could be developed within the basin. That proposal also recognized the need to transfer water from the Forebay Area to the Pressure and East Side Areas. The solution proposed in 1946 remains the best solution even today.

We urge the MCWRA to focus its attention on the completion of the original plan by the construction and operation of water transfer facilities. The MCWRA should avoid diverting its attention to suggested alternatives that are less viable economically or less effective technically. These less viable and less effective alternatives would <u>not</u> provide the same benefits as the original plan, would be more expensive, and the projected price of water would be significantly higher for all parties.

The panel believes strongly that Salinas Valley is fortunate that an in-Valley solution is available. We urge the Salinas Valley community to support the MCWRA in this effort to distribute the available water supplies for more efficient water management and lasting benefits for all residents of the Valley.

Re: Public Comment Letter for the Langley Aquifer Subbasin Draft GSP

Dear Donna Meyers,

On behalf of the above-listed organizations, we appreciate the opportunity to comment on the Draft Groundwater Sustainability Plan (GSP) for the Langley Aquifer Subbasin being prepared under the Sustainable Groundwater Management Act (SGMA). Our organizations are deeply engaged in and committed to the successful implementation of SGMA because we understand that groundwater is critical for the resilience of California's water portfolio, particularly in light of changing climate. Under the requirements of SGMA, Groundwater Sustainability Agencies (GSAs) must consider the interests of all beneficial uses and users of groundwater, such as domestic well owners, environmental users, surface water users, federal government, California Native American tribes and disadvantaged communities (Water Code 10723.2).

As stakeholder representatives for beneficial users of groundwater, our GSP review focuses on how well disadvantaged communities, drinking water users, tribes, climate change, and the environment were addressed in the GSP. While we appreciate that some basins have consulted us directly via focus groups, workshops, and working groups, we are providing public comment letters to all GSAs as a means to engage in the development of 2022 GSPs across the state. Recognizing that GSPs are complicated and resource intensive to develop, the intention of this letter is to provide constructive stakeholder feedback that can improve the GSP prior to submission to the State.

Based on our review, we have significant concerns regarding the treatment of key beneficial users in the Draft GSP and consider the GSP to be **insufficient** under SGMA. We highlight the following findings:

1. Beneficial uses and users **are not sufficiently** considered in GSP development.
    a. Human Right to Water considerations **are not sufficiently** incorporated.
    b. Public trust resources **are not sufficiently** considered.
    c. Impacts of Minimum Thresholds, Measurable Objectives and Undesirable Results on beneficial uses and users **are not sufficiently** analyzed.
2. Climate change **is not sufficiently** considered.
3. Data gaps **are not sufficiently** identified and the GSP **needs additional plans** to eliminate them.
4. Projects and Management Actions **do not sufficiently consider** potential impacts or benefits to beneficial uses and users.

Our specific comments related to the deficiencies of the Langley Aquifer Subbasin Draft GSP along with recommendations on how to reconcile them, are provided in detail in **Attachment A.**

Please refer to the enclosed list of attachments for additional technical recommendations:

Attachment A	GSP Specific Comments
Attachment B	SGMA Tools to address DAC, drinking water, and environmental beneficial uses and users
Attachment C	Freshwater species located in the basin
Attachment D	The Nature Conservancy's "Identifying GDEs under SGMA: Best Practices for using the NC Dataset"
Attachment E	Maps of representative monitoring sites in relation to key beneficial users

Thank you for fully considering our comments as you finalize your GSP.

Attachment A

Specific Comments on the Langley Aquifer Subbasin Draft Groundwater Sustainability Plan

1. Consideration of Beneficial Uses and Users in GSP development

Consideration of beneficial uses and users in GSP development is contingent upon adequate identification and engagement of the appropriate stakeholders. The (A) identification, (B) engagement, and (C) consideration of disadvantaged communities, drinking water users, tribes, groundwater dependent ecosystems, streams, wetlands, and freshwater species are essential for ensuring the GSP integrates existing state policies on the Human Right to Water and the Public Trust Doctrine.

A. Identification of Key Beneficial Uses and Users

Disadvantaged Communities and Drinking Water Users

The identification of Disadvantaged Communities (DACs) and drinking water users is **incomplete**. The GSP provides information on DACs, including identification by name and location on a map (Figure 2-3), and identifying the water source for DAC members. However, the GSP fails to identify the population of each identified DAC.

The GSP provides a density map of domestic wells in the subbasin. However, the GSP fails to provide depth of these wells (such as minimum well depth, average well depth, or depth range) within the subbasin.

These missing elements are required for the GSA to fully understand the specific interests and water demands of these beneficial users, and to support the development of sustainable management criteria and projects and management actions that are protective of these users.

RECOMMENDATIONS
● Include a map showing domestic well locations and average well depth across the subbasin. ● Provide the population of each identified DAC.

Interconnected Surface Waters

The identification of Interconnected Surface Waters (ISW) is **insufficient**, due to lack of supporting information provided for the ISW analysis. To assess ISWs, the GSP used the Salinas Valley Integrated Hydrologic Model (SVIHM). The GSP states (p. 4-22): *"Although seepage along the ISW reaches is based on assumed channel and aquifer parameters as model inputs, the preliminary SVIHM is the best available tool to estimate ISW locations. The model construction and uncertainty are described in Chapter 6 of this GSP."* However, Chapter 6 of the GSP, the water budget chapter, presents very little information on the model. No further information in the GSP was presented providing description of the location of groundwater wells or stream gauges used in the analysis, or description of temporal (seasonal and interannual) variability of the data used to calibrate the model.

The GSP states (p. 4-22): *"The blue cells [in Figure 4-9] indicate areas where surface water is connected to groundwater for more than 50 percent of the number of months in the model period and are designated as areas of ISW. The clear cells represent areas that have interconnection less than 50 percent of the model period and require further evaluation to determine whether the SMC, discussed in Chapter 8, apply."* Note the regulations [23 CCR §351(o)] define ISW as "surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted". "At any point" has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water. The GSP states (p. 4-22): "Interconnection between surface water and groundwater can vary both in time and space. A seasonal analysis is included in Appendix 4A." The appendix was not included in the public draft copy of the GSP, however.

RECOMMENDATIONS

- Describe available groundwater elevation data and stream flow data in the subbasin. ISWs are best analyzed using depth-to-groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought), to determine the range of depth and capture the variability in environmental conditions inherent in California's climate.

- Overlay the stream reaches shown on Figure 4-9 with depth-to-groundwater contour maps to illustrate groundwater depths and the groundwater gradient near the stream reaches. Show the location of groundwater wells in the subbasin used to create the contour maps.

- For the depth-to-groundwater contour maps, use the best practices presented in Attachment D. Specifically, ensure that the first step is contouring groundwater elevations, and then subtracting this layer from land surface elevations from a Digital Elevation Model (DEM) to estimate depth-to-groundwater contours across the landscape. This will provide accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found.

- On Figure 4-9 (Locations of Interconnected Surface Water), consider any modelled stream grid cells with >0% connection to groundwater as potential ISWs until more data is available. In other words, consider any stream cell with connection to groundwater for any length of time as a potential ISW.

- Describe data gaps for the ISW analysis. Reconcile these data gaps with specific measures (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features in the Monitoring Network section of the GSP.

Groundwater Dependent Ecosystems

The identification of Groundwater Dependent Ecosystems (GDEs) is **insufficient**, due to a lack of comprehensive, systematic analysis of the subbasin's GDEs.

The GSP took initial steps to identify and map GDEs using the Natural Communities Commonly Associated with Groundwater dataset (NC dataset) and other sources. The GSP does not discuss how the NC dataset was verified with the use of groundwater data, however. The GSP states (p. 4-26): "*The SVBGSA reviewed the NCCAG dataset and assessed each GDE's potential* *connection to groundwater by determining if the GDE was underlain by shallow groundwater that has been delineated as being part of a Bulletin 118 principal aquifer, and if depth to groundwater is less than 30 feet."* However, no further details are provided in the GSP. Based on the description provided in the GSP, it is unclear if Figure 4-10 (Groundwater Dependent Ecosystems) presents the entire NC dataset, or further analysis based on the 30 feet threshold as described in the text. Without an analysis of groundwater data to verify the NC dataset polygons, it will be difficult or impossible to adequately monitor and manage the subbasin's GDEs throughout GSP implementation.

We commend the GSA for listing the threatened and endangered species likely to depend on groundwater, as determined from several sources including the US Fish and Wildlife Service (USFWS) website, California Department of Fish and Wildlife (CDFW) California Natural Diversity Database (CNDDB), and TNC Critical Species LookBook (Table 4-1). Vegetation species present in the subbasin's potential GDEs were not included in the GSP, however.

RECOMMENDATIONS

- Develop and describe a systematic approach for analyzing the subbasin's GDEs. For example, provide a map of the NC Dataset. On the map, label polygons retained, removed, or added to/from the NC dataset (include the removal reason if polygons are not considered potential GDEs, or include the data source if polygons are added). Discuss how local groundwater data was used to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. Refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.

- Use depth-to-groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. We recommend that a baseline period (10 years from 2005 to 2015) be established to characterize groundwater conditions over multiple water year types. Refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.

- Refer to Attachment B for more information on TNC's plant rooting depth database. Deeper thresholds are necessary for plants that have reported maximum root depths that exceed the averaged 30-ft threshold, such as valley oak (*Quercus lobata*). We recommend that the reported max rooting depth for these deeper-rooted plants be used. For example, a depth-to-groundwater threshold of 80 feet should be used instead of the 30-ft threshold, when verifying whether valley oak polygons from the NC Dataset are connected to groundwater. It is important to re-emphasize that actual rooting depth data are limited and will depend on the plant species and site-specific conditions such as soil and aquifer types, and availability to other water sources.

- Provide depth-to-groundwater contour maps, noting the best practices presented in Attachment D. Specifically, ensure that the first step is contouring groundwater elevations, and then subtracting this layer from land surface elevations from a digital elevation model (DEM) to estimate depth-to-groundwater contours across the landscape.

- If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons as “Potential GDEs” in the GSP until data gaps are reconciled in the monitoring network.

- Please provide a complete inventory, map, or description of fauna (e.g., birds, fish, amphibian) and flora (e.g., plants) species in the subbasin (see Attachment C of this letter for a list of freshwater species located in the Langley Subbasin).

Native Vegetation and Managed Wetlands

Native vegetation and managed wetlands are water use sectors that are required[1,2] to be included in the water budget. The integration of native vegetation into the water budget is **insufficient**. The water budget includes a separate item for evapotranspiration, but based on the text it is unclear whether the values shown in the budget tables apply to riparian evapotranspiration only or contain crop evapotranspiration as well. The omission of explicit water demands for native vegetation is problematic because key environmental uses of groundwater are not being accounted for as water supply decisions are made using this budget, nor will they likely be considered in project and management actions. The GSP states that managed wetlands are not present in the subbasin.

RECOMMENDATION

- Quantify and present all water use sector demands in the historical, current, and projected water budgets with individual line items for each water use sector, including native vegetation.

B. Engaging Stakeholders

Stakeholder Engagement during GSP development

Stakeholder engagement during GSP development is **incomplete**. SGMA’s requirement for public notice and engagement of stakeholders[3] is not fully met by the description in the Communication and Public Engagement section of the GSP (Chapter 2).

The GSA’s outreach activities include conducting interviews with DAC community leaders to identify strategies to work together during GSP planning and implementation; conducting workshops with partners on water and groundwater sustainability; identifying concerns from DACs and underrepresented communities; planning listening sessions around GSA milestones; developing a resource hub with partner organizations; identifying community allies to partner with

[1] “’Water use sector’ refers to categories of water demand based on the general land uses to which the water is applied, including urban, industrial, agricultural, managed wetlands, managed recharge, and native vegetation.” [23 CCR §351(al)]

[2] “The water budget shall quantify the following, either through direct measurements or estimates based on data: (3) Outflows from the groundwater system by water use sector, including evapotranspiration, groundwater extraction, groundwater discharge to surface water sources, and subsurface groundwater outflow.” [23 CCR §354.18]

[3] “A communication section of the Plan shall include a requirement that the GSP identify how it encourages the active involvement of diverse social, cultural, and economic elements of the population within the basin.” [23 CCR §354.10(d)(3)]

in reducing barriers to participation from DACs; and planning to convene a working group on domestic water that includes DACs and underrepresented communities. However, there is no specific pathway for feedback from DAC residents and representatives to be considered and included in the GSP and its implementation.

We note additional deficiencies with the overall stakeholder engagement process. While environmental organizations have a representative serving on the board of directors and are listed as stakeholders and as members of the GSP Advisory Committee, there is no specific outreach described that is directly targeted to environmental stakeholders during the GSP development and implementation processes.

RECOMMENDATIONS

- In the Communication and Public Engagement Plan, describe active and targeted outreach to engage environmental stakeholders during the remainder of the GSP development process and throughout the GSP implementation phase. Refer to Attachment B for specific recommendations on how to actively engage stakeholders during all phases of the GSP process.

- DAC and environmental stakeholder engagement should be improved by incorporating feedback and recommendations from DAC and environmental stakeholders engaged in the GSP process.

C. Considering Beneficial Uses and Users When Establishing Sustainable Management Criteria and Analyzing Impacts on Beneficial Uses and Users

The consideration of beneficial uses and users when establishing sustainable management criteria (SMC) is **insufficient**. The consideration of potential impacts on all beneficial users of groundwater in the basin are required when defining undesirable results[4] and establishing minimum thresholds.[5,6]

Disadvantaged Communities and Drinking Water Users

For chronic lowering of groundwater levels, the GSP discusses minimum thresholds impact on domestic wells (Section 8.6.2.2). The GSP states (p. 8-14): *"In the Langley Subbasin, 85% of the domestic wells will have at least 25 feet of water in them as long as groundwater elevations remain above minimum thresholds and measurable objectives. These percentages were considered reasonable despite the limitations of this analysis."* The GSP states (p. 8-8): *"The minimum thresholds for chronic lowering of groundwater levels are set to 2019 groundwater elevations, adjusted based on well-specific elevation assessments."* The GSP does not explain the rationale behind using 2019 groundwater elevation data instead of data from the period before the SGMA benchmark date of 2015.

[4] "The description of undesirable results shall include [...] potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results." [23 CCR §354.26(b)(3)]

[5] "The description of minimum thresholds shall include [...] how minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests." [23 CCR §354.28(b)(4)]

[6] "The description of minimum thresholds shall include [...] how state, federal, or local standards relate to the relevant sustainability indicator. If the minimum threshold differs from other regulatory standards, the agency shall explain the nature of and the basis for the difference." [23 CCR §354.28(b)(5)]

Section 8.6.4 defines undesirable results for the chronic lowering of groundwater level SMC. The GSP states (p. 8-20): *"The chronic lowering of groundwater levels undesirable result is: more than 15% of the groundwater elevation minimum thresholds are exceeded."* However, undesirable results should inform the development of minimum thresholds, not the other way around. The GSP should establish minimum thresholds at the representative monitoring wells that account for the specific undesirable results the GSA has determined for the subbasin. The current analysis, which only considers 41 out of 823 wells, is insufficient and does not use best available information, for example including Public Land Survey System (PLSS) section location data, as was used in the 180/400 Foot Aquifer GSP.

For degraded water quality, the GSP identifies constituents of concern (COCs) within the subbasin. The GSP states (p. 5-21): *"The SVBGSA does not have regulatory authority over groundwater quality and is not charged with improving groundwater quality in the Salinas Valley Groundwater Basin."* Table 8-4 provides a list of constituents and number of wells that must exceed regulatory standards in order to trigger minimum thresholds but fails to provide justification for how those numbers were selected. The GSP also sets measurable objectives identical to minimum thresholds; the exceedance of minimum thresholds is supposed to trigger additional actions but since minimum thresholds in this plan are identified as measurable objectives, it is unclear what action is triggered. Furthermore, the regulatory standards are not explicitly provided in the GSP.

RECOMMENDATIONS

Chronic Lowering of Groundwater Levels

- Describe direct and indirect impacts on DACs and drinking water users when defining undesirable results for chronic lowering of groundwater levels. For the analysis of minimum threshold impact on domestic wells, use best available information such as Public Land Survey System (PLSS) section location data.

- Establish minimum thresholds at the representative monitoring wells that account for the specific undesirable results the GSA would like to avoid. Use groundwater level data from the period before the SGMA benchmark date of 2015 for the analysis.

Degraded Water Quality

- Describe direct and indirect impacts on DACs and drinking water users when defining undesirable results for degraded water quality. For specific guidance on how to consider these users, refer to "Guide to Protecting Water Quality Under the Sustainable Groundwater Management Act."[7]

- Set measurable objectives at lower levels than minimum thresholds (i.e., indicative of better water quality).

---

[7] Guide to Protecting Water Quality under the Sustainable Groundwater Management Act https://d3n8a8pro7vhmx.cloudfront.net/communitywatercenter/pages/293/attachments/original/1559328858/Guide_to_Protecting_Drinking_Water_Quality_Under_the_Sustainable_Groundwater_Management_Act.pdf?1559328858.

- Set concentration-based minimum thresholds and measurable objectives for COCs in the subbasin that are impacted by groundwater use and/or management. Ensure they align with drinking water standards[8].
- Evaluate the cumulative or indirect impacts of proposed minimum thresholds for degraded water quality on DACs and drinking water users.

Groundwater Dependent Ecosystems and Interconnected Surface Waters

Sustainable management criteria for chronic lowering of groundwater levels provided in the GSP do not consider potential impacts to environmental beneficial users. The GSP neither describes nor analyzes direct or indirect impacts on environmental users of groundwater when defining undesirable results. This is problematic because without identifying potential impacts to GDEs, minimum thresholds may compromise, or even destroy, these environmental beneficial users. Since GDEs are present in the subbasin, they must be considered when developing SMC.

Sustainable management criteria for depletion of interconnected surface water are established by proxy using shallow groundwater elevations observed in 2019 near locations of interconnected surface water. To describe impacts to ecological surface water users, the GSP states (p. 8-49): *"There are no known flow prescriptions on any surface water bodies in the Subbasin. Therefore, the current level of depletion has not violated any ecological flow requirements. This is not meant to imply that depletions do not impact potential species living in or near surface water bodies in the Subbasin. However, any impacts that may be occurring have not risen to the level that triggers regulatory intervention. Therefore, the impacts from current rates of depletion on ecological surface water users is not unreasonable."* The GSP makes no attempt to evaluate the impacts of the proposed minimum threshold on environmental beneficial users of surface water. The GSP does not explain how the chosen minimum thresholds and measurable objectives avoid significant and unreasonable effects on surface water beneficial users in the subbasin, such as increased mortality and inability to perform key life processes (e.g., reproduction, migration).

RECOMMENDATIONS

- When defining undesirable results for chronic lowering of groundwater levels, provide specifics on what biological responses (e.g., extent of habitat, growth, recruitment rates) would best characterize a significant and unreasonable impact to GDEs. Undesirable results to environmental users occur when 'significant and unreasonable' effects on beneficial users are caused by one of the sustainability indicators (i.e., chronic lowering of groundwater levels, degraded water quality, or depletion of interconnected surface water). Thus, potential impacts on environmental beneficial uses and users need to be considered when defining undesirable results[9] in the subbasin. Defining undesirable results is the crucial first step before the minimum thresholds[10] can be determined.

---

[8] "Degraded Water Quality [...] collect sufficient spatial and temporal data from each applicable principal aquifer to determine groundwater quality trends for water quality indicators, as determined by the Agency, to address known water quality issues." [23 CCR §354.34(c)(4)]

[9] "The description of undesirable results shall include [...] potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results". [23 CCR §354.26(b)(3)]

[10] The description of minimum thresholds shall include [...] how minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests." [23 CCR §354.28(b)(4)]

- When defining undesirable results for depletion of interconnected surface water, include a description of potential impacts on instream habitats within ISWs when minimum thresholds in the subbasin are reached[11]. The GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of interconnected surface waters as these environmental users could be left unprotected by the GSP. These recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law[6,12].

2. Climate Change

The SGMA statute identifies climate change as a significant threat to groundwater resources and one that must be examined and incorporated in the GSPs. The GSP Regulations[13] require integration of climate change into the projected water budget to ensure that projects and management actions sufficiently account for the range of potential climate futures.

The integration of climate change into the projected water budget is **insufficient**. The GSP does incorporate climate change into the projected water budget using DWR change factors for 2030 and 2070. However, the GSP does not consider multiple climate scenarios (e.g., the 2070 extremely wet and extremely dry climate scenarios) in the projected water budget. The GSP should clearly and transparently incorporate the extremely wet and dry scenarios provided by DWR into projected water budgets or select more appropriate extreme scenarios for their basins. While these extreme scenarios may have a lower likelihood of occurring, their consequences could be significant, therefore they should be included in groundwater planning.

We acknowledge and commend the inclusion of climate change into key inputs (e.g., precipitation, evapotranspiration, surface water flow, and sea level) of the projected water budget. However, the GSP does not calculate a sustainable yield based on the projected water budget with climate change incorporated. If the water budgets are incomplete, including the omission of extremely wet and dry scenarios, and sustainable yield is not calculated based on climate change projections, then there is increased uncertainty in virtually every subsequent calculation used to plan for projects, derive measurable objectives, and set minimum thresholds. Plans that do not adequately include climate change projections may underestimate future impacts on vulnerable beneficial users of groundwater such as ecosystems, DACs, and domestic well owners.

---

11 "The minimum threshold for depletions of interconnected surface water shall be the rate or volume of surface water depletions caused by groundwater use that has adverse impacts on beneficial uses of the surface water and may lead to undesirable results." [23 CCR §354.28(c)(6)]

12 Rohde MM, Seapy B, Rogers R, Castañeda X, editors. 2019. Critical Species LookBook: A compendium of California's threatened and endangered species for sustainable groundwater management. The Nature Conservancy, San Francisco, California. Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/Critical_Species_LookBook_91819.pdf

13 "Each Plan shall rely on the best available information and best available science to quantify the water budget for the basin in order to provide an understanding of historical and projected hydrology, water demand, water supply, land use, population, climate change, sea level rise, groundwater and surface water interaction, and subsurface groundwater flow." [23 CCR §354.18(e)]

RECOMMENDATIONS

- Integrate climate change, including extremely wet and dry scenarios, into all elements of the projected water budget to form the basis for development of sustainable management criteria and projects and management actions.
- Calculate sustainable yield based on the projected water budget with climate change incorporated.
- Incorporate climate change scenarios into projects and management actions.

3. Data Gaps

The consideration of beneficial users when establishing monitoring networks is **insufficient**, due to lack of specific plans to increase the Representative Monitoring Sites (RMSs) in the monitoring network that represent shallow groundwater elevations around DACs and domestic wells in the subbasin. The monitoring network that represents water quality conditions around DACs and domestic wells in the subbasin is sufficient in terms of spatial distribution but is insufficient in terms of depth representation.

Figure 7-1 (Langley Area Representative Monitoring Network for Groundwater Levels) shows that no monitoring wells are located across portions of the subbasin near DACs and domestic wells. Beneficial users of groundwater may remain unprotected by the GSP without adequate monitoring and identification of data gaps in the shallow aquifer. The Plan therefore fails to meet SGMA's requirements for the monitoring network[14].

The GSP provides discussion of data gaps for GDEs and ISWs in Section 7.7 (Interconnected Surface Water Monitoring Network) of the GSP. The GSP could be improved by describing biological monitoring that could be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

RECOMMENDATIONS

- Provide maps that overlay monitoring well locations with the locations of DACs and domestic wells to clearly identify potentially impacted areas. Increase the number of representative monitoring sites (RMSs) in the shallow aquifer across the subbasin for the groundwater elevation and groundwater quality condition indicators. Prioritize proximity to DACs and drinking water users when identifying new RMSs.
- Describe biological monitoring that can be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.
- Ensure groundwater elevation and water quality RMSs are tracking groundwater conditions spatially and at the correct depth for *all* beneficial users - especially DACs, domestic wells, GDEs, and ISWs. Groundwater elevation and quality RMS data gaps

[14] "The monitoring network objectives shall be implemented to accomplish the following: [...] (2) Monitor impacts to the beneficial uses or users of groundwater." [23 CCR §354.34(b)(2)]

(spatial and depth) in relation to key beneficial users in the subbasin are provided in Attachment E.

4. Addressing Beneficial Users in Projects and Management Actions

The consideration of beneficial users when developing projects and management actions is **insufficient**, due to the failure to completely identify benefits or impacts of identified projects and management actions to key beneficial users of groundwater such as GDEs, aquatic habitats, surface water users, DACs, and drinking water users. Therefore, potential project and management actions may not protect these beneficial users. Groundwater sustainability under SGMA is defined not just by sustainable yield, but by the avoidance of undesirable results for *all* beneficial users.

The GSP states (p. 8-14): *"In the Langley Subbasin, 85% of the domestic wells will have at least 25 feet of water in them as long as groundwater elevations remain above minimum thresholds and measurable objectives."* Therefore, up to 15% of domestic wells could be impacted when water levels drop below measurable objectives, and even more could be impacted when water levels reach minimum thresholds. In Section 9.5.3 (Implementation Action D3: Dry Well Notification System), the GSP states (p. 9-46): *"The GSA could develop or support the development of a program to assist well owners (domestic or state small and local small water systems) whose wells go dry due to declining groundwater elevations."* The GSP states that the program could involve a notification system, monitoring triggered by lowered groundwater elevations, public outreach, *"...referral to assistance with short-term supply solutions, technical assistance to assess why it went dry, and/or long-term supply solutions."* No further specifics on a drinking water well impact mitigation program are provided, however.

RECOMMENDATIONS

- For DACs and domestic well owners, provide specific plans for implementation of a drinking water well impact mitigation program to proactively monitor and protect drinking water wells through GSP implementation. Refer to Attachment B for specific recommendations on how to implement a drinking water well mitigation program.

- For DACs and domestic well owners, include a discussion of whether potential impacts to water quality from projects and management actions could occur and how the GSA plans to mitigate such impacts.

- Recharge ponds, reservoirs, and facilities for managed stormwater recharge can be designed as multiple-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. For guidance on how to integrate multi-benefit recharge projects into your GSP, refer to the "Multi-Benefit Recharge Project Methodology Guidance Document"[15].

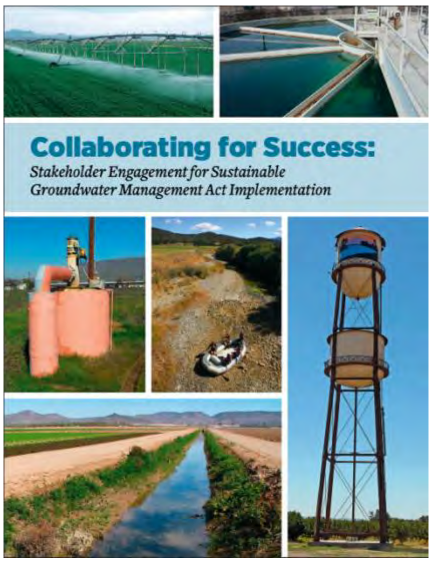
- Develop management actions that incorporate climate and water delivery uncertainties to address future water demand and prevent future undesirable results.

[15] The Nature Conservancy. 2021. Multi-Benefit Recharge Project Methodology for Inclusion in Groundwater Sustainability Plans. Sacramento. Available at: https://groundwaterresourcehub.org/sgma-tools/multi-benefit-recharge-project-methodology-guidance/

Attachment B

SGMA Tools to address DAC, drinking water, and environmental beneficial uses and users

Stakeholder Engagement and Outreach



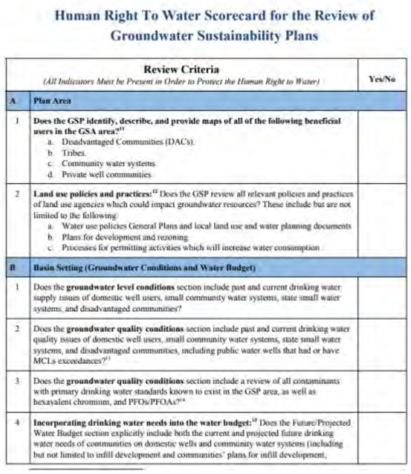
Clean Water Action, Community Water Center and Union of Concerned Scientists developed a guidance document called Collaborating for success: Stakeholder engagement for Sustainable Groundwater Management Act Implementation. It provides details on how to conduct targeted and broad outreach and engagement during Groundwater Sustainability Plan (GSP) development and implementation. Conducting a targeted outreach involves:

- Developing a robust Stakeholder Communication and Engagement plan that includes outreach at frequented locations (schools, farmers markets, religious settings, events) across the plan area to increase the involvement and participation of disadvantaged communities, drinking water users and the environmental stakeholders.

- Providing translation services during meetings and technical assistance to enable easy participation for non-English speaking stakeholders.

- GSP should adequately describe the process for requesting input from beneficial users and provide details on how input is incorporated into the GSP.

The Human Right to Water

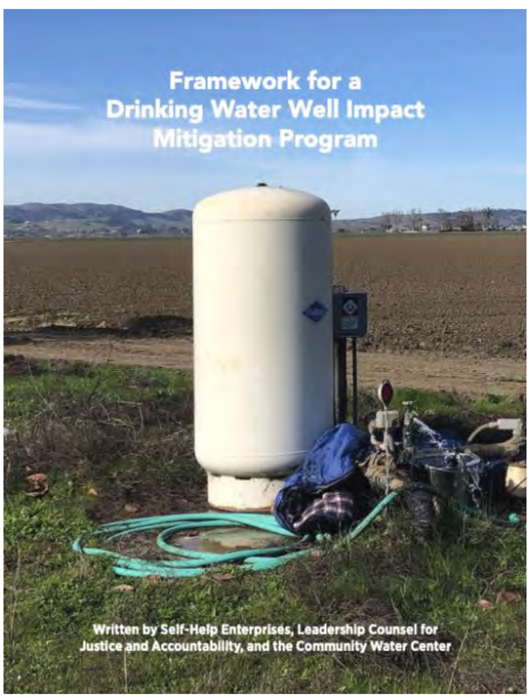


Human Right To Water Scorecard for the Review of Groundwater Sustainability Plans

	Review Criteria *(All Indicators Must be Present in Order to Protect the Human Right to Water)*	**Yes/No**
A	**Plan Area**	
1	**Does the GSP identify, describe, and provide maps of all of the following beneficial users in the GSA area?**[11] a. Disadvantaged Communities (DACs). b. Tribes. c. Community water systems d. Private well communities	
2	**Land use policies and practices:**[12] Does the GSP review all relevant policies and practices of land use agencies which could impact groundwater resources? These include but are not limited to the following: a. Water use policies General Plans and local land use and water planning documents b. Plans for development and rezoning c. Processes for permitting activities which will increase water consumption	
B	**Basin Setting (Groundwater Conditions and Water Budget)**	
1	Does the **groundwater level conditions** section include past and current drinking water supply issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities?	
2	Does the **groundwater quality conditions** section include past and current drinking water quality issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities, including public water wells that had or have MCLs exceedances?[13]	
3	Does the **groundwater quality conditions** section include a review of all contaminants with primary drinking water standards known to exist in the GSP area, as well as hexavalent chromium, and PFOs/PFOAs?[14]	
4	**Incorporating drinking water needs into the water budget:**[15] Does the Future/Projected Water Budget section explicitly include both the current and projected future drinking water needs of communities on domestic wells and community water systems (including but not limited to infill development and communities' plans for infill development.	

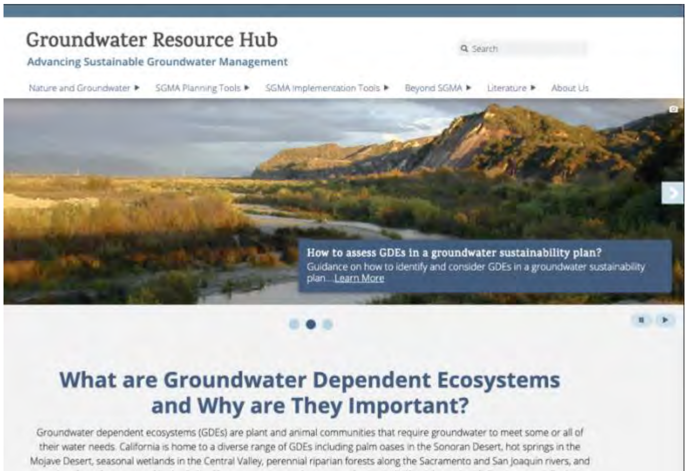
The Human Right to Water Scorecard was developed by Community Water Center, Leadership Counsel for Justice and Accountability and Self Help Enterprises to aid Groundwater Sustainability Agencies (GSAs) in prioritizing drinking water needs in SGMA. The scorecard identifies elements that must exist in GSPs to adequately protect the Human Right to Drinking water.

Drinking Water Well Impact Mitigation Framework



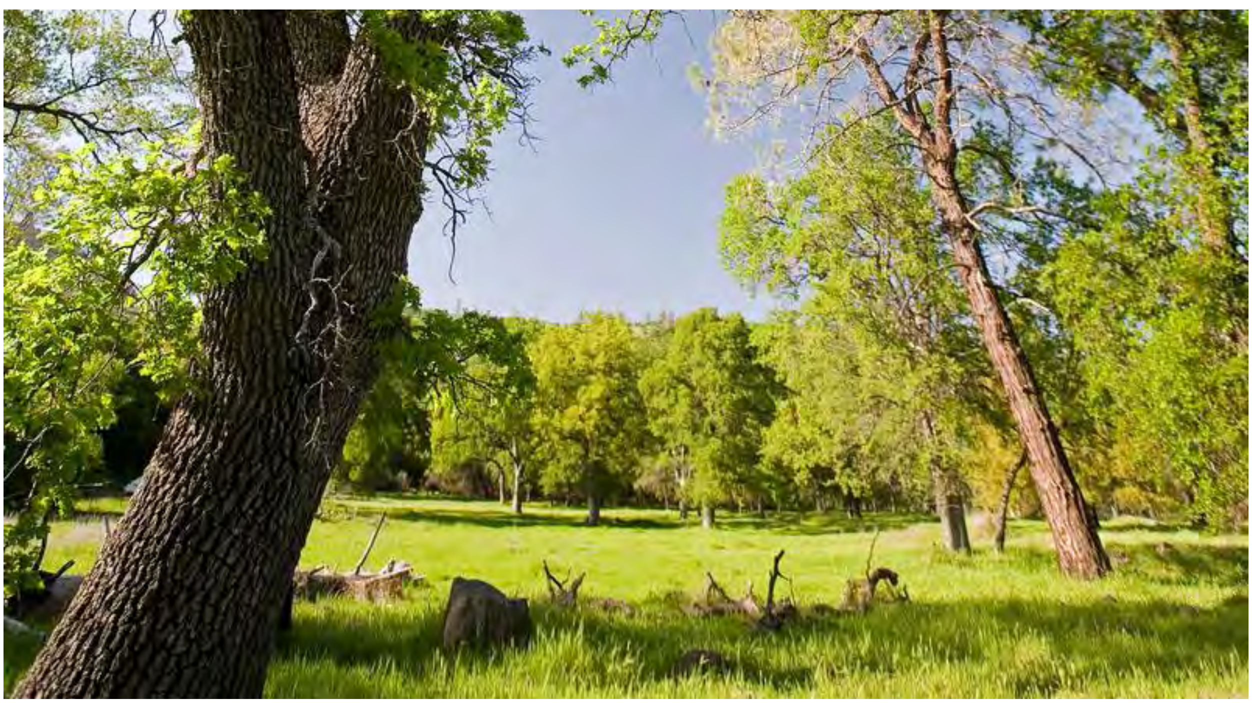
The Drinking Water Well Impact Mitigation Framework was developed by Community Water Center, Leadership Counsel for Justice and Accountability and Self Help Enterprises to aid GSAs in the development and implementation of their GSPs. The framework provides a clear roadmap for how a GSA can best structure its data gathering, monitoring network and management actions to proactively monitor and protect drinking water wells and mitigate impacts should they occur.

Groundwater Resource Hub



The Nature Conservancy has developed a suite of tools based on best available science to help GSAs, consultants, and stakeholders efficiently incorporate nature into GSPs. These tools and resources are available online at GroundwaterResourceHub.org. The Nature Conservancy's tools and resources are intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Rooting Depth Database



The Plant Rooting Depth Database provides information that can help assess whether groundwater-dependent vegetation are accessing groundwater. Actual rooting depths will depend on the plant species and site-specific conditions, such as soil type and availability of other water sources. Site-specific knowledge of depth to groundwater combined with rooting depths will help provide an understanding of the potential groundwater levels are needed to sustain GDEs.

How to use the database

The maximum rooting depth information in the Plant Rooting Depth Database is useful when verifying whether vegetation in the Natural Communities Commonly Associated with Groundwater (NC Dataset) are connected to groundwater. A 30 ft depth-to-groundwater threshold, which is based on averaged global rooting depth data for phreatophytes[1], is relevant for most plants identified in the NC Dataset since most plants have a max rooting depth of less than 30 feet. However, it is important to note that deeper thresholds are necessary for other plants that have reported maximum root depths that exceed the averaged 30 feet threshold, such as valley oak (*Quercus lobata*), Euphrates poplar (*Populus euphratica*), salt cedar (*Tamarix spp.*), and shadescale (*Atriplex confertifolia*). The Nature Conservancy advises that the reported max rooting depth for these deeper-rooted plants be used. For example, a depth-to groundwater threshold of 80 feet should be used instead of the 30 ft threshold, when verifying whether valley oak polygons from the NC Dataset are connected to groundwater. It is important to re-emphasize that actual rooting depth data are limited and will depend on the plant species and site-specific conditions such as soil and aquifer types, and availability to other water sources.

The Plant Rooting Depth Database is an Excel workbook composed of four worksheets:

1. California phreatophyte rooting depth data (included in the NC Dataset)
2. Global phreatophyte rooting depth data
3. Metadata
4. References

How the database was compiled

The Plant Rooting Depth Database is a compilation of rooting depth information for the groundwater-dependent plant species identified in the NC Dataset. Rooting depth data were compiled from published scientific literature and expert opinion through a crowdsourcing campaign. As more information becomes available, the database of rooting depths will be updated. Please Contact Us if you have additional rooting depth data for California phreatophytes.

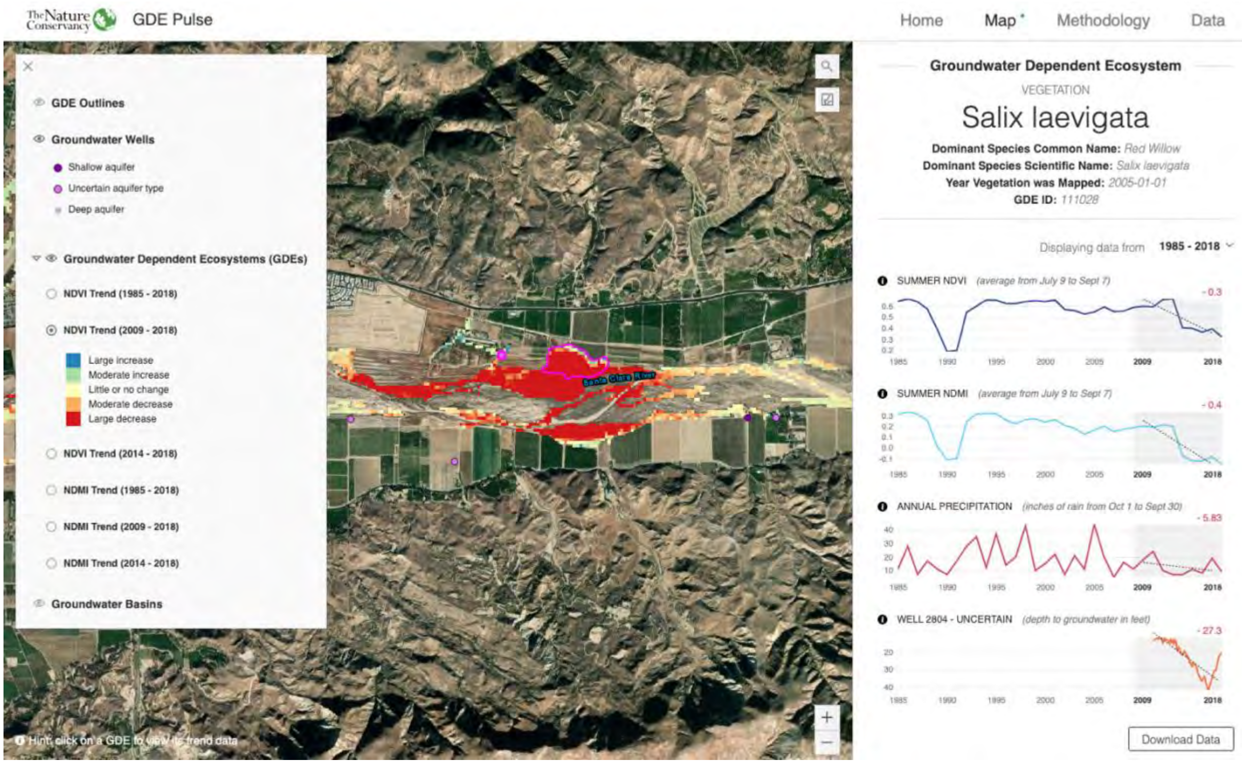
GDE Pulse



GDE Pulse is a free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data. Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset. The following datasets are available for downloading:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

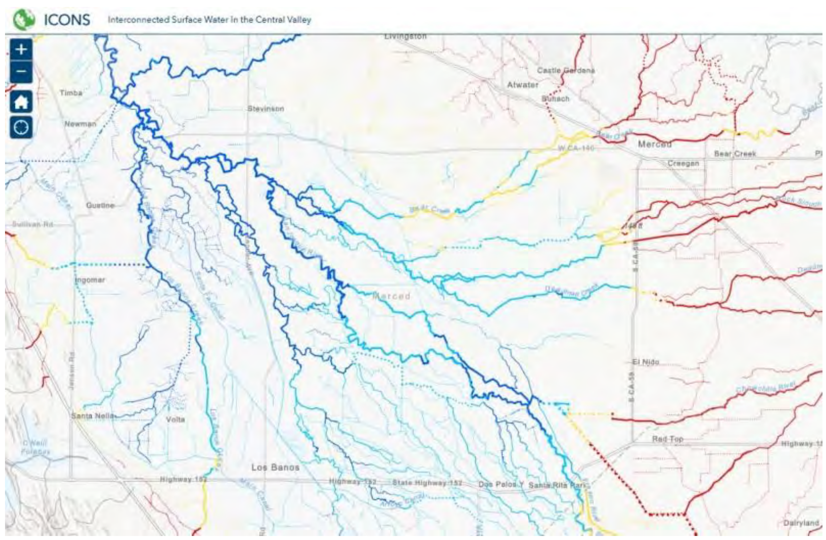
Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

ICONOS Mapper

Interconnected Surface Water in the Central Valley



ICONS maps the likely presence of interconnected surface water (ISW) in the Central Valley using depth to groundwater data. Using data from 2011-2018, the ISW dataset represents the likely connection between surface water and groundwater for rivers and streams in California's Central Valley. It includes information on the mean, maximum, and minimum depth to groundwater for each stream segment over the years with available data, as well as the likely presence of ISW based on the minimum depth to groundwater. The Nature Conservancy developed this database, with guidance and input from expert academics, consultants, and state agencies.

We developed this dataset using groundwater elevation data available online from the California Department of Water Resources (DWR). DWR only provides this data for the Central Valley. For GSAs outside of the valley, who have groundwater well measurements, we recommend following our methods to determine likely ISW in your region. The Nature Conservancy's ISW dataset should be used as a first step in reviewing ISW and should be supplemented with local or more recent groundwater depth data.

Attachment C

Freshwater Species Located in the Langley Area Basin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Langley Area Basin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the basin boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[1]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[2] as well as on The Nature Conservancy's science website[3].

Scientific Name	Common Name	Legal Protected Status		
		Federal	State	Other
BIRDS				
Agelaius tricolor	Tricolored Blackbird	Bird of Conservation Concern	Special Concern	BSSC - First priority

IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[1] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[2]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.

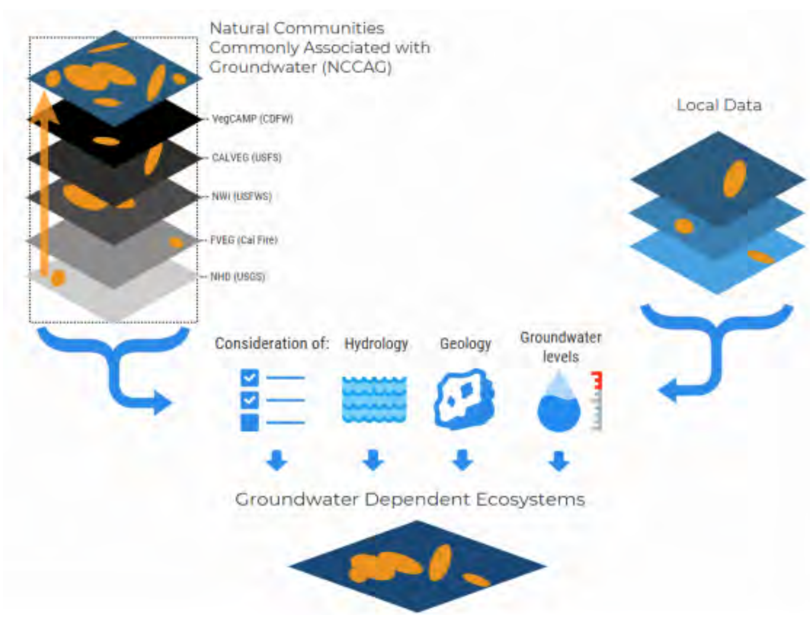

Figure 1. Considerations for GDE identification.
Source: DWR[2]

[1] NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/
[2] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[3]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[4] on the Groundwater Resource Hub[5], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

[5] The Groundwater Resource Hub: www.GroundwaterResourceHub.org

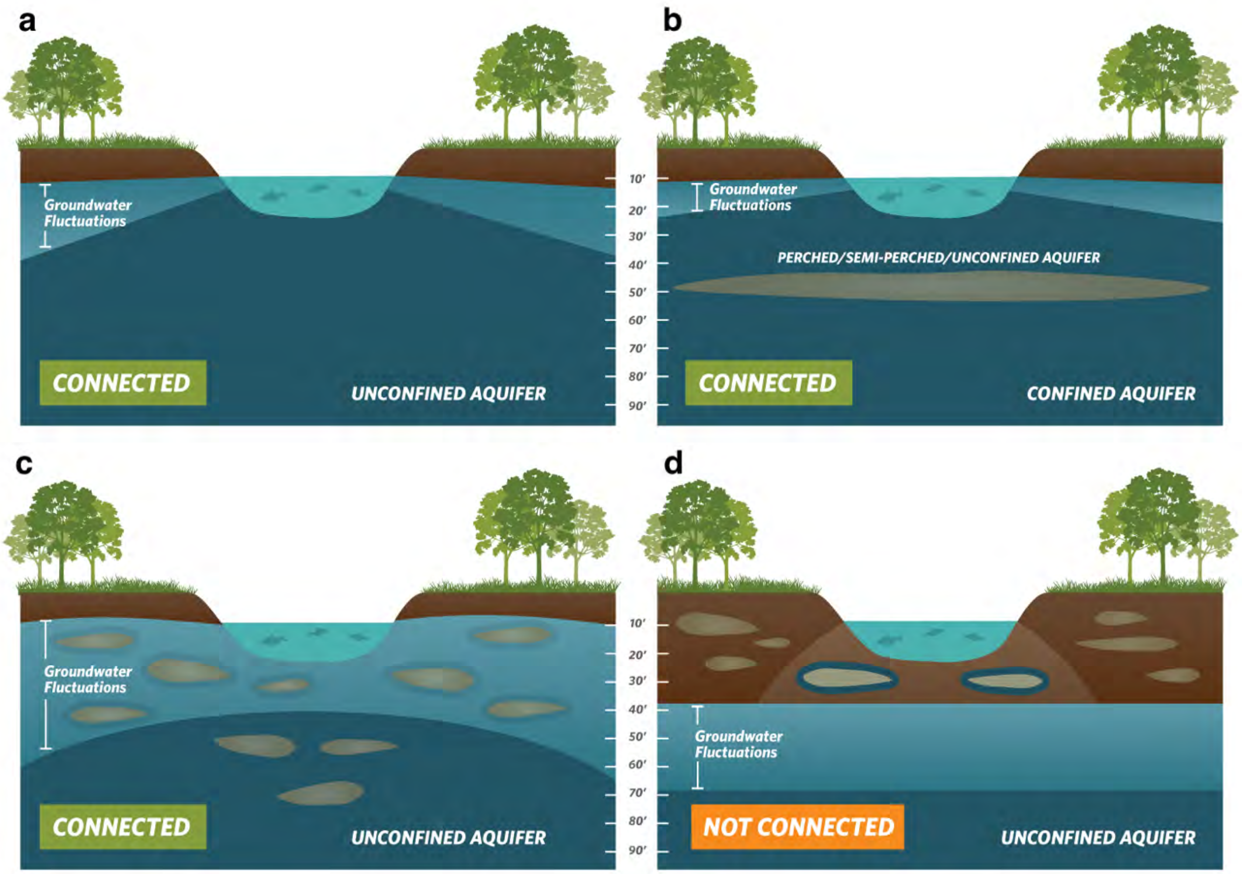

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. (b) Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. Bottom: (c) Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. (d) Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[6] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[7] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[8] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[9]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

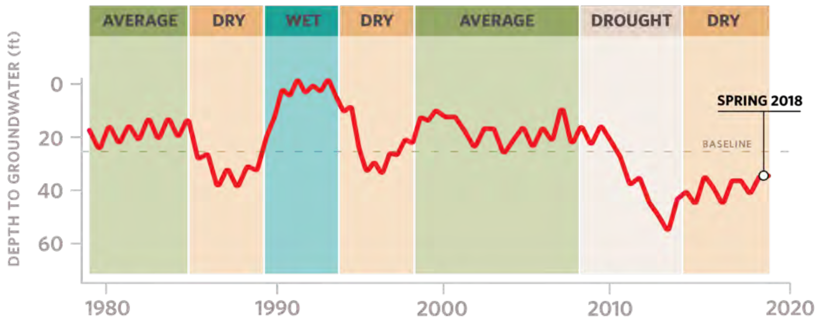

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

---

[6] DWR. 2016. Water Budget Best Management Practice. Available at: https://water.ca.gov/LegacyFiles/groundwater/sgm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

[7] Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]

[8] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[9] SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[10], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

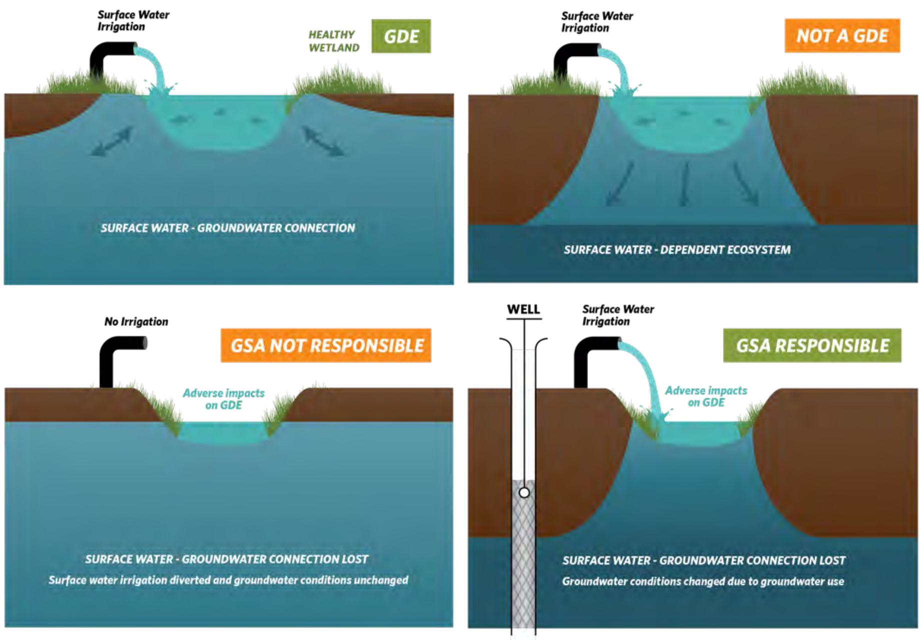

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. (Right) Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. Bottom: (Left) An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. (Right) Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

---

[10] For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

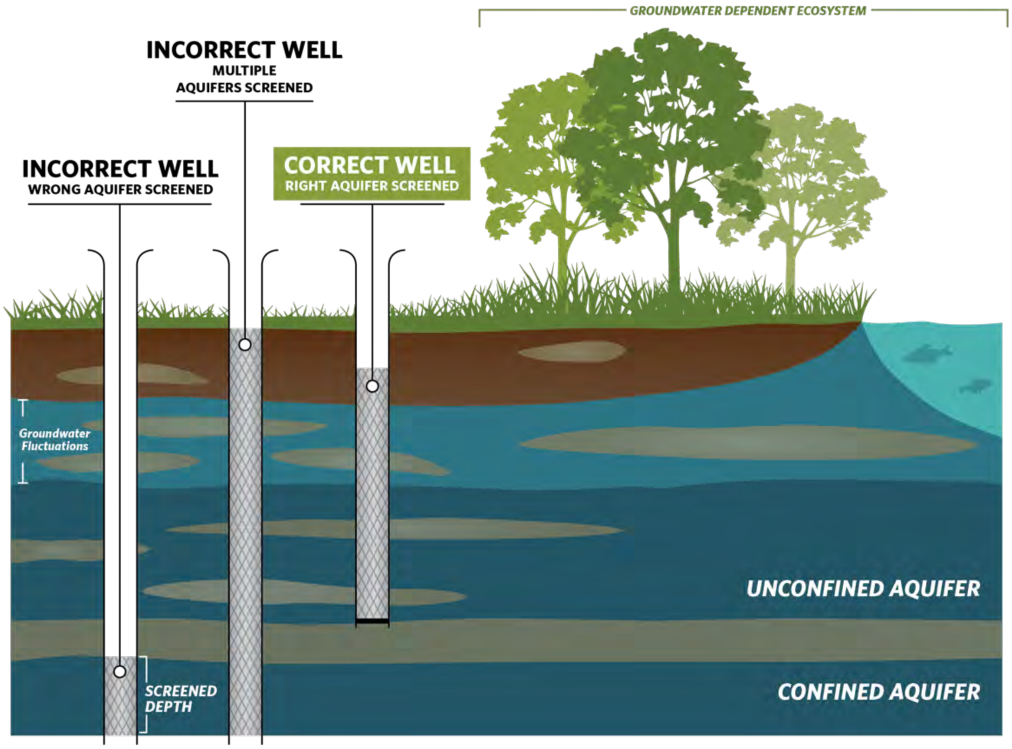

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[11] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

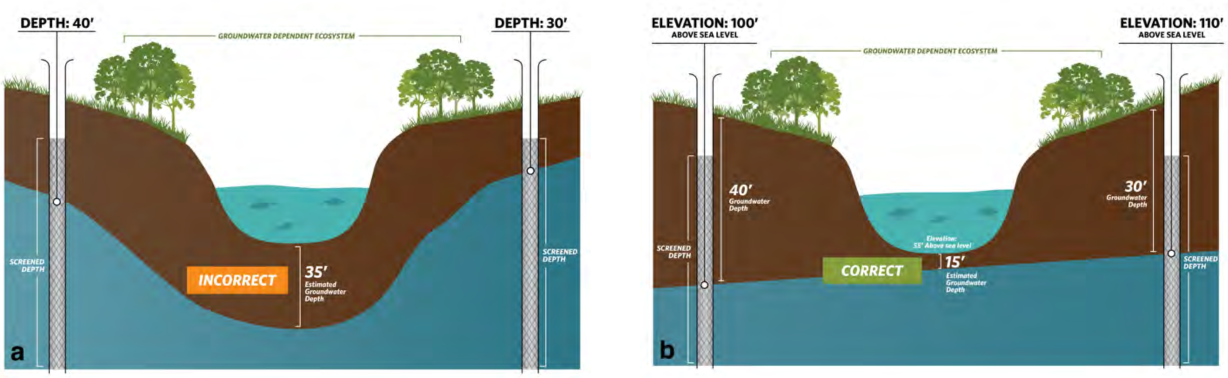

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. (b) Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

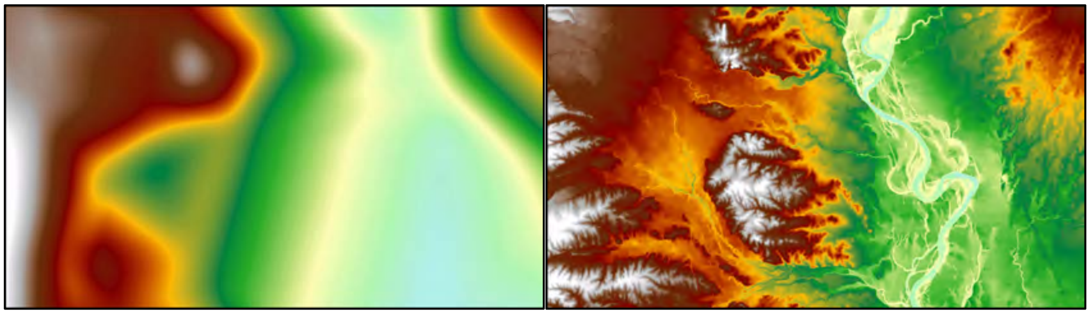

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. (Right) Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[11] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network. Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Attachment E

Maps of representative monitoring sites in relation to key beneficial users

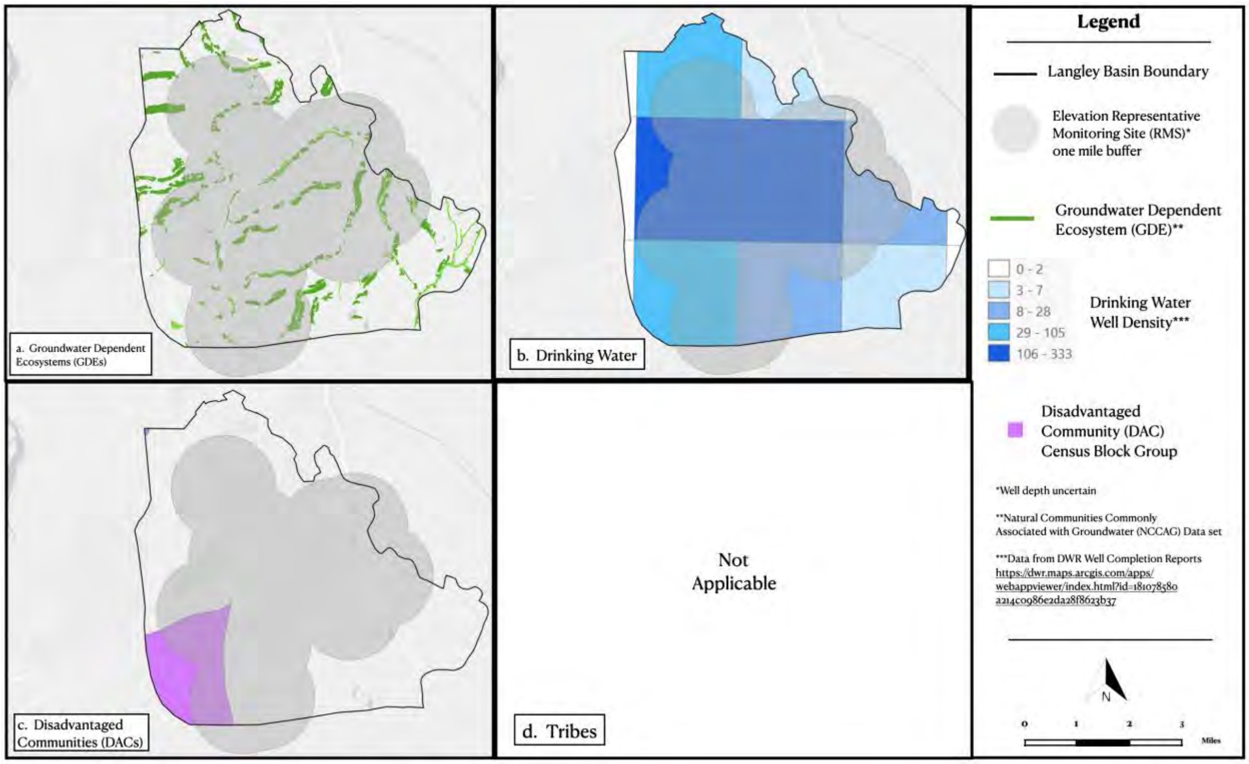

Figure 1. Groundwater elevation representative monitoring sites in relation to key beneficial users: a) Groundwater Dependent Ecosystems (GDEs), b) Drinking Water users, c) Disadvantaged Communities (DACs), and d) Tribes.

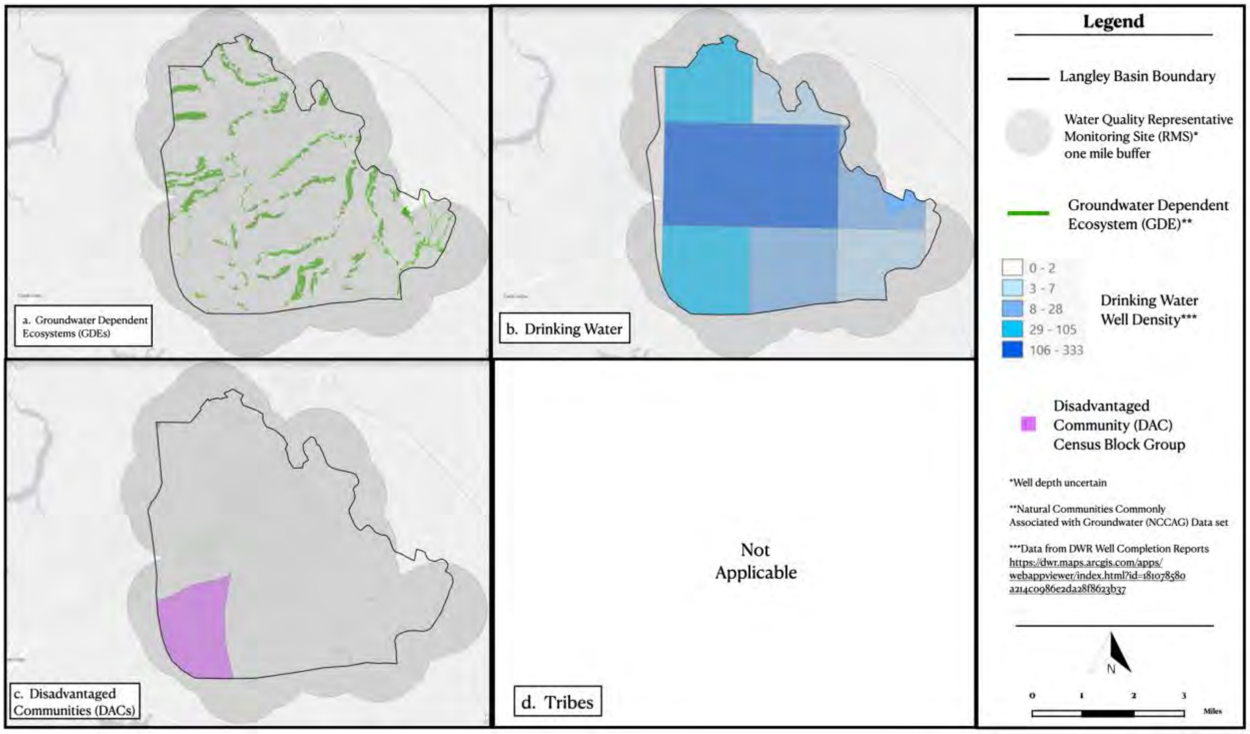

Figure 2. Groundwater quality representative monitoring sites in relation to key beneficial users: a) Groundwater Dependent Ecosystems (GDEs), b) Drinking Water users, c) Disadvantaged Communities (DACs), and d) Tribes.

PAGE NO./SECTION NO.	SUGGESTED WORDING TO BE ADDED (NEW WORDING SHOWN IN RED, EXISTING WORDING IS IN BLACK)
6-10/6.1	Transient boundary conditions tied to historical water level observations (within the 180/400 Foot Aquifer Subbasin), simulated water levels from existing groundwater flow models (within the Seaside Area Subbasin this refers to the Watermaster's Seaside Basin Groundwater Flow Model developed by HydroMetrics/Montgomery & Associates), and freshwater equivalent sea levels (along the Monterey Coast);
6-15/6.2.2	Subsurface exchanges with the Seaside Area Subbasin are calculated by the MBGWFM using a general head boundary condition. The MBGWFM calculates subsurface flow based on modeled groundwater head outputs at the Seaside boundary from the historical Seaside Basin Groundwater Flow Model (Hydrometrics 2009 & 2018) and lateral hydraulic conductivities at boundary cells. Translating modeled boundary conditions from the Seaside Subbasin to the Monterey Subbasin is not completely accurate because the MBGWFM has a single model layer representing the Paso Robles and Santa Margarita aquifers, whereas the Seaside Basin model has each aquifer as a separate model layer. Early GSP implementation will include improving the MBGWFM boundary conditions so that the two models have more closely aligned hydrogeologic conditions at their shared boundary.
6-23/6.4.1.1.3	918 AFY of net annual inflows from the Seaside Subbasin into the Monterey Subbasin. These flows are represented as positive in Table 6-1 because even though there are both inflows and outflows from Seaside basin to the Monterey Subbasin, overall there is net inflow from the Seaside Subbasin to the Monterey Subbasin. Estimates of the magnitude of these inflows is ~~generally~~ not consistent with those estimated by the Seaside Basin Groundwater Flow Model (Hydrometrics 2009 & 2018). The probable reason for this is discussed in Section 6.2.2, which also identifies the modeling limitations to be addressed within the first five years of GSP implementation.
6-28/6.4.2.1.3	1,310 AFY of net annual inflows from the Seaside Subbasin into the Marina-Ord Area WBZ.
6-33/6.4.3.1.3	392 AFY of net annual outflows from the Corral de Tierra Area WBZ into the Seaside Subbasin.
6-36/6.5.1	Seaside Basin Groundwater Flow Model. Final (September 2018) historical groundwater elevations output from the Seaside model (Hydrometrics 2009 & 2018) were used to develop projected groundwater elevations at the Seaside Area Subbasin boundary. As discussed in Section 6.2.2, the model boundary condition heads output from the Seaside Basin Groundwater Flow Model represent the Paso Robles and Santa Margarita aquifers separately, while the MBGWFM combines those into one model layer. It is recognized the translation of heads is inaccurate because of the model layer differences between the two models. The MBGWFM's boundary condition assumptions will be improved to address the issue within this first five years of GSP implementation

6-38/6.5.1.3	Each of these boundary condition scenarios are predicated on the assumption that (a) the 180/400 Foot Aquifer subbasin will be managed to its SMCs over the 50-year projected model period and (b) Seaside subbasin, which is an adjudicated subbasin, will be managed sustainably such that groundwater levels remain stable into the future. However, the Seaside Basin Watermaster's modeling (using the Seaside Basin Groundwater Flow Model) found that it would be impossible for the Laguna Seca subarea of the Seaside subbasin to be managed such that groundwater levels would remain stable in that subarea in the future. The reason for this is that even if all pumping within the Laguna Seca Subarea were to be discontinued (an infeasible undertaking) groundwater would flow in an easterly direction out of the Laguna Seca subarea and into the Corral de Tierra subarea. This would be caused by low groundwater levels in the Corral de Tierra subarea compared to groundwater levels in the easterly portion of the Laguna Seca subarea. This highlights the importance of raising groundwater levels within the Corral de Tierra in order to not impede the ability of the Seaside subbasin to be sustainably managed.
6-39/6.5.1.3	The Seaside basin is subject to adjudication requirements that require that rates of groundwater extraction within the Subbasin not exceed the estimated basin safe yield. As such, in all three boundary conditions scenarios, groundwater levels in the adjudicated Seaside basin are assumed to remain stable into the future. However, as noted in Section 6.7, and contrary to the language in Section 6.5.1.3, the Seaside Basin Watermaster predictive modeling of the Laguna Seca subarea of the Seaside subbasin found that groundwater levels in the eastern portion of the Laguna Seca subarea could not be managed such that groundwater levels would remain stable, even if all pumping in the Laguna Seca subarea stopped, because of the effects of pumping in the Corral de Tierra Subarea. This boundary condition assumption discrepancy will be addressed and resolved during the early stage of implementation of the GSP. Water levels along the Seaside Subbasin boundary have been set to model predicted values at the end of the Historical Period (i.e., September 2018) in the Marina-Ord Area or at the established MTs (i.e. based on ~~2015~~ 2008 water levels) in the Corral de Tierra Area wherever they were below MTs at the end of the Historical Period.
6-49/6.5.4.1.3	However, inflows from the Seaside Basin will also be significantly influenced by groundwater levels in the Seaside basin, which have been assumed to stay constant at 2018 levels[10]. However, as noted in Section 6.7, and contrary to the language in Section 6.5.1.3, the Seaside Basin Watermaster's predictive modeling found that it would be impossible for the Laguna Seca subarea of the Seaside subbasin to be managed such that groundwater levels would remain stable in that subarea. Further analysis of potential inflows and outflows along the Seaside subbasin boundary is proposed as part of proposed future modeling efforts identified in implementation action Future Modeling of Seawater Intrusion and Projects, Section 9.5.6.
6-63/6.7	*Incomplete conceptualization of Principal Aquifer units in the Seaside Basin Groundwater Flow Model.* The Seaside model does not explicitly simulate groundwater flow from each principal aquifer unit defined in the Monterey

	Subbasin GSP, but rather uses a unique conceptualization of aquifer units that is primarily based on the main geologic formations encountered in the Seaside Area Subbasin (i.e., the Aromas Sands, Paso Robles Formation, and Santa Margarita/Purisima Formations). As such, there is considerable uncertainty surrounding the assumptions employed to link outputs from the Seaside model to individual layers of the MBGWFM[15], which may impact resulting calculations of Seaside Area Subbasin exchanges within the water budget. Further analysis of potential inflows and outflows along the Seaside subbasin boundary is proposed as part of proposed future modeling efforts identified in implementation action Future Modeling of Seawater Intrusion and Projects, Section 9.5.6.

Groundwater Sustainability Planning

Name	Erika Marx
Organization	US Army Presidio of Monterey
Email Address	erika.r.marx.civ@mail.mil
Chapter	9
Section	Table 9-1 (M2)
Page Number(s)	395
Comments	The US Army Garrison Presidio of Monterey (USAG POM) is currently developing plans to decommission a 66-inch diameter stormwater outfall located within the Fort Ord Dunes State Park. The outfall, owned by USAG POM, currently discharges stormwater collected from approximately 4,657 acres that span multiple jurisdictions, including USAG POM (Ord Military Community), City of Seaside, State Parks, and Bureau of Land Management. Cumulative discharge volumes range from 21 AF (85th percentile storm event) up to 364 AF (100-year storm event). USAG POM (Ord Military Community) contributes approximately 7% of the total runoff volume. USAG POM is planning to install a percolation pond to manage the runoff from the Ord Military Community only (excluding privatized military housing areas); all other jurisdictions that discharge stormwater to the outfall will be required to implement their own stormwater management alternatives. The outfall decommissioning and construction of the percolation pond is anticipated to occur in FY25. USAG POM is interested in discussing with the GSA whether this percolation pond could be beneficial to the GSP. Depending on the location, the percolation pond could potentially contribute to subbasin recharge.

Subject: Marina Coast Water District, Draft Groundwater Sustainability Plan, Monterey Subbasin, dated September 2021

Dear Mr. Scherzinger:

Thank you for the opportunity to provide comment on the MCWD GSA Draft Groundwater Sustainability Plan for the Monterey Subbasin. We appreciate the effort that has gone into the preparation of this draft. (Note for ease of searching the page numbers listed here reflect the electronic pdf pagination and not the page numbers printed in the document.)

Page 19 Section 2.3.1 Local Land Use Planning Agencies: As a state entity, California State University Monterey Bay has exclusive land use planning jurisdiction and sovereign authority over its lands and facilities, and should be added to and described in this section. Alternatively, and more precisely, a separate section should be included titled “State Government Stakeholders,” describing CSUMB as a state entity with exclusive land use planning jurisdiction and authority over land and facilities it owns and/or controls.

Page 36, Figure 3-2: The area shown in purple and labelled “California State University Monterey Bay” should be shown in light green to denote state jurisdiction.

Page 40 3.1.5: California State University Monterey Bay has sovereign and land use planning authority over the land it owns or controls within the Subbasin.

Page 55 MCWD 2020 Urban water management plan: The second paragraph is very unclear, is the demand short of the supply or is the supply short to satisfy the demand ? In Ord there only appears to be a 10 AFY difference between the projected demand of 6,610 AFY and 6,600 AFY supply, yet a number of 1,693 AFY is portrayed as the difference between something and something? The paragraph only begins to have a semblance of making sense when footnote 10 is taken into account. The paragraph should be rewritten to bring that crucial footnoted information into the body of the text and to clarify the meaning.

Page 55 MCWD 2020 Urban water management plan: Third paragraph given that the shortfall portrayed is really not Ord Community wide but only occurs on an allocated jurisdictional basis, and there is more than one jurisdiction that is projected to exceed their allocation, the “potential shortfall” should be referred to as “potential jurisdictional shortfalls” (plural).

Page 56: Bullet points

Commercial, Industrial and Institutional accounts: Unlike the other bullet points on this page this one is devoid of any substance that bears on demand management measures, it is simply a list of some the different user classes the District has identified within its customer base with no description of any relationship to demand management practices.

Page 62 section 3.5: CSUMB as an entity of the State of California has sovereign and land use authority over the lands and facilities it owns and/or controls that are in the Monterey Subbasin.

Page 71: Suggest add a section "3.5.1.6 CSUMB Master Plan" as follows:
California State University, Monterey Bay (CSUMB) is in the process of updating its approved Master Plan with one with a 2035 planning horizon. The proposed CSUMB Master Plan (proposed Master Plan), includes Project Design Features (PDFs) drawn from the CSUMB Master Plan Guidelines (based on the 2017 public draft Comprehensive Master Plan) and provides the basis for the physical development of the campus. It provides a blueprint for land uses and building and facility space requirements to support an on-campus enrollment of 12,700 full-time-equivalent students and 1,776 FTE faculty and staff.

The proposed Master Plan strives to meet 11 objectives that include "conserve natural resources and ecosystem services and connect people to the natural environment" as well as implement multiple PDFs that conserve water and promote resiliency.

Water supply and wastewater collection service is currently provided by the Marina Coast Water District (MCWD) within the Ord Community service area. Both CSUMB's proposed Master Plan buildout and MCWD's Urban Water Management Plan demonstrate there is adequate water available for the buildout of the proposed Master Plan.

Page 72: 3.5.2 : Suggest add a bullet point as follows:
"The CSUMB master plan strategy relative to water demand is to grow the campus within its existing water allocations while being conscious of the effect of potential subbassin wide management actions affecting water allocations in aggregate. The University remains engaged in the success of the GSP, but retains the autonomy vested in it as a state entity to determine how to allocate its limited resources in order to best accomplish its educational mission. The University remains open to participation in projects and management actions that set the stage for future growth beyond its current master plan and beyond the forecast identified in the 2020 MCWD UWMP, but so long as the University can realize current and future plans within these forecasts and allocations, participation will be a result of voluntary decisions, not as a result of an imposed regime.

Page 72 3.5.3: need to distinguish between "new development" which could be defined as new developments not entitled as of time of writing versus "new developments" that exceed a jurisdiction's allocation, or allocation as modified by this GSP. The latter definition should be applied in arriving at "fees levied on such new developments"

Page 211 analog years 41-50 are shown as 1999-2008, is 2008 a typo of 2018 ? If not, then an explanation would be warranted.

Page 264 Groundwater Elevation Monitoring Network: A number of wells established by the U.S. Army on lands now under the jurisdiction of CSUMB were or still are operated for the specific purpose of Base Cleanup and Re-use. The U.S. Army is responsible for closure of the wells and removal of the encumbrance on the property records when the wells are no longer needed for that purpose. It should not be assumed that these wells will transition to the monitoring network without the express permission of CSUMB when the U.S. Army's clean-up objectives are achieved. This comment is also directly applicable to the footnote on page 10-5 indicating that MCWD plans to obtain ownership of wells once the Army's remediation efforts terminate. Any transfer of well ownership as opposed to closure, will be from Army to current fee title owner of property, MCWD may negotiate for ownership or use with the fee title holder.

Page 310 8.1 Definitions: At first glance it seems like the first two sustainability indicators "chronic lowering of groundwater levels" and "reduction of groundwater storage" are so closely inter related as they may really be a single indicator. However, it becomes clear later in the SMC section that sea water intrusion can cause a reduction in groundwater storage via a change in water composition. A note or footnote elucidating the reader at this point might be beneficial.

Page 311 8.2 Sustainability Goal: Limiting the sustainability goal of the Monterey subbasin to benefiting its "residents and businesses" appears to exclude other constituencies, such as state entities, from benefiting from the goal of the plan. It also neglects the established political subdivisions and processes that distill the many opinions that may exist within the communities that overly the subbasin on what a benefit consists of, or valuing tradeoffs that may need to be made. Suggest the language be modified to "The sustainability goal of the Monterey Subbasin is to manage groundwater resources for long-term community, financial , and environmental benefits to the subbasins communities as determined by their respective land use ownership and jurisdictions" noting the previous comments on the inclusion of CSUMB, as sovereign authority over land and facilities it owns and/or controls.

The listing of potential projects and management actions prior to any discussion of SMC's, of what constitutes undesirable result or an estimation of the likelihood of the occurrence of undesirable result in the document is premature and seems intended to lead to a conclusion. Suggest projects and management actions only be discussed in Chapter 9.

Page 316 Table 8-1:
"Chronic lowering of groundwater levels" The undesirable result language is unclear because of the use of the word "exceedance" and "more" to define undesirable results. If the intent is that an undesirable result occurs when ground water levels become 20% BELOW those identified in the minimum threshold column then simpler to state that.

"Reduction in groundwater storage": Given that criteria is stated in the table for elevation change it is suggested this table state the corresponding criteria for sea water intrusion thresholds.

"Seawater intrusion:" The sea water intrusion thresholds are stated here

The first three Sustainable Management Criteria SMC's seem to have an interdependency and overlap that results in an unnecessary complication of SMC's.
SMC 1: ground water level
SMC 2: ground water level and sea water intrusion
SMC 3: sea water intrusion

Suggest get rid of SMC 2

"Subsidence:" Minimum Threshold is stated as "Long Term" yet performance measurement is year over year and not cumulative which seems at odds with "Long Term".

Depletion of ISW: How was the two consecutive year parameter arrived at for the undesirable result ? If there is a high correlation between ISW and annual precipitation and figure 6.3 shows runs of up to six years of below average precipitation is two years too short a timeframe ?

Pages 325-334 Presentation Measurable Objective (MO) and Minimum Threshold (MT) and Historical charts of ground water elevations relative to): The intent of establishing an MO and MT is to be able to measure performance against established target values and to be able to gauge that performance relatively based on how near or how far current readings are from the MO and MT. However, it appears that the methodology used for selecting MO and MT from historical data in some cases yield MO's and MT's that are in fact very close to each (in a few cases they are the same). Having MO's and MT's that are very near each other appears to defeat the purpose of being able to describe relative performance. Put another way if a reading is near the MO things are going well and if a reading is below the MT things are going poorly, when the MO and MT are very close to each other or the same, and a reading that is below either value is obtained what does that really mean? Suggest some minimum separation of MO and MT be established and that some significance be attached to how much a value is distant from MO or MT.

Page 335: should paragraph 2 read "to verify seawater intrusion does NOT expand?"

Page 343 8.7.3.8: The minimum thresholds are targets established by the GSP, they are not measured (they may have been derived from past measurements). Actual water elevation readings are taken from the RMS Network and compared against the corresponding Minimum Threshold target to determine performance.

Page 343 Measurable objectives: This paragraph seems to support that the MO should be different than the MT.

Page 346 8.7.4.2 Interim Milestones: The prefacing of this section with "projects" is again jumping to conclusions. One would have expected a discussion of current conditions of each sustainability indicator relative to its MO, MT and Undesirable Result prior to a discussion of interim milestones or projects. Milestones is an indication that a course of action has been undertaken, when so far, the discussion has only been around historical information and the establishment of a monitoring framework.

Page 352 8.8.2.1 and 8.8.2.2: Seems to confirm that SMC #2 is redundant.

Page 363 8.10.2.3 Effects on Beneficial Users and Land Use: The paragraph's meaning is unclear. Is it intended to state that the SMC will limit selected GSP projects, or limit selected land use development projects within the GSP area? If the projects are "selected" then there appears to be some knowledge of which these are, if so they should be stated.

Page 371 "ecological land uses and users": Should the paragraph read "it can be inferred that PREVENTION OF the degradation of ground water quality minimum thresholds provide generally positive benefits…" (follow on: do the thresholds degrade or does the water quality degrade and approach the thresholds?)

Page 373 8.11.3.1: Given that the Subsidence minimum thresholds are set by the measurement error of the available data gathering tools suggest that as the first investigational step of 8.11.2.1 be to re-verify the accuracy of the measurements.

Second paragraph "or other projects are implemented within the Valley." "the Valley" is not a defined term and has not figured in the 392 pages of discussion so far. Needs clarification.

Third Paragraph: Suggest "should view these POTENTIAL projects and management actions"

Fourth paragraph: Suggest following language "Specific approaches for implementing management actions and projects will provide individual landowners and public entities, notably land use jurisdictions, flexibility in how they manage water use within their control in support of the Subbasin achieving groundwater sustainability"

Page 395 P/MA# M1: It should not be assumed that any reduction in groundwater use as a result of management actions will provide long term in lieu recharge as many land use jurisdictions will simply re-deploy their FORA ground water allocations to new development unless the management action prevents them from doing so by holding the jurisdictions to their allocations or proportionally reducing allocations.

Page 395 P/MA# M2: As stated it is not clear how existing policies will result in a beneficial change. Assuming that rainfall is constant how will the existing policies improve stormwater catchment and infiltration over the current situation? The management action implies there is currently an inefficiency that will be eliminated, but it would behoove to inform.

Page 396 P/MA# M3: It should not be assumed that 100% of groundwater water use converted to recycled irrigation provides long term in-lieu recharge as many land use jurisdictions intend to redeploy their FORA ground water allocations to new development when they are freed up by application of recycled. The 600 AFY and 827 AFY having already been allocated to land use jurisdiction by FORA only subsequent projects are likely to provide net recharge. The cost responsibility for those projects should be proportional to a jurisdiction's planned exceedance of its allocations.

Page 402 Evaluation of Benefits: It is crucial to be clear that project benefit (or lack thereof) is tied directly to water quantity or availability. Because the longstanding planning yardstick of availability to land use jurisdictions on the former Fort Ord are the FORA water allocations, both potable and recycled, it stands that any measure of project benefit will need to be taken against those underlying allocation numbers on a jurisdictional basis. The narrative seems to assume that projects will occur and that the alternate hypothetical condition is one where projects did not occur. This seems backwards, the base case should be no project, and the negative impacts to allocations evaluated, similarly to the procedure described in 9.4.8 “pumping allocations and controls” proposed for the Coral de Tierra area. A project case can then be presented and each jurisdiction can choose to participate and receive the positive benefit, or can choose not to participate and suffer the negative benefit. Participation in a project is not just conceptual, it is financial, and jurisdictions need to understand that. It is unlikely that future participation will exactly mirror the current FORA allocations, or current usage relative to allocations, therefore the share of benefit between jurisdictions will never be equal, which will mean that the financial contributions of the customer bases in each jurisdiction will need to be different, i.e. different rates and capacity charges will need to apply in each jurisdiction.

Another way of looking at this is that MCWD 2020 UWMP page 27 table 4.5 indicates that some jurisdiction wills be below their FORA allocations at the end of the forecast period, while some will be over. Those jurisdictions that will be below their allocations will essentially be voluntarily providing in-lieu recharge, similarly to management action M1. Those jurisdictions providing in-lieu recharge in this form should receive some form of consideration as compared to those jurisdictions that are exceeding their allocations, thereby contributing more to any potential overdraft condition, when determining project benefit.

Page 437, Recycled Water generation, collection and treatment: Suggest explicitly identify the change in operational responsibility and ownership of infrastructure when the waste water enters the M1W system that runs along the coast. As it reads, it appears MCWD conveys waste water all the way to the treatment plant.

Page 438 Landscape Irrigation: If MCWD truly intends to deliver recycled water for irrigation in 2022 as stated, then some more concrete actions towards converting existing users that already have agreements to receive such water might be warranted. Note Page 440 indicates 2023, there seems to be some confusion, and on page 442 its back to 2022.

Page 441, 9.4.6.4 Public Noticing: California State University Monterey Bay should be listed as a key stakeholder. See also above comments.

Page 506 10.7 Plan Implementation Costs:

The planning level costs identified in the first 7 bullet points of this section appear appropriate for inclusion in standard rates and charges for water delivered to MCWD customers, much as the cost of ensuring the safety of drinking water is today. Caution should be exercised in ensuring that this new cost is spread evenly over all water used and not heavily loaded on one class of user or tier of usage. Additionally, the inclusion of costs to support adjacent subbasins, notably listed as TBD, is concerning. Each subbasin bears the cost responsibility for managing itself, while technical cooperation between basins is understood to be needed suggest that this potential expenditure be capped at some percentage of overall Monterey Subbasin management expense.

page 513: It is notable that despite its apparently greater challenges in reaching sustainability the estimated 5 year operating cost to the SVBGSA for the Coral de Tierra area at $1,398,000 is 37% of the proposed MCWD 5 year operating cost for the MCWD area.

Page 514 10.7.3 Funding for Projects and Management Actions:
The projected water budget demand for the Marina-Ord WBZ is the District’s approved 2020 UMWP which includes growth in every jurisdiction that receives water from the Monterey Subbasin, such growth increasing water demand from 3,376 AFY to 9,584 AFY (MCWD 2020 UWMP page 27 table 4.5) . The draft Monterey subbassin GSP also concludes that even with this growth the Marina-Ord WBZ will not be in overdraft so long as adjacent subbasins are

managed sustainably. Taken together these statements indicate that any future overdraft in the Marina Ord WBZ that result in projects or management actions will be due to growth by the jurisdictions or by failure of the adjacent subbasins to meet their GSP management objectives. Because a significant component (and perhaps the exclusive component) of the need for projects (that result in infrastructure) or management actions (intended to avoid infrastructure investment by instituting practices and procedures that yield similar benefit), is supporting growth, the associated costs are in effect "Capacity Charges" regardless of the form in which they are collected. By virtue of the San Marcos Legislation (Gov't Code 54999 et Seq) State Agencies and Educational Facilities such as CSU are not required to pay Capacity Charges unless an agreement is reached with the imposing public utility/entity and such agreement results in charges to CSU that are nondiscriminatory, meaning that they fund only facilities that benefit CSU and such funding reflects CSU's proportionate share of cost relative to CSU's proportionate share of use/benefit. CSU has expressed a willingness to negotiate capacity charge agreements for Water, Sewer and Recycled Water with the District and would extend this willingness to GSP projects and management actions when they are better defined.

Overall, and as a matter of general comment, there is no mention in this 516+page GSP of the court's recent ruling regarding MCWD's rate structure. In *Bay View Community DE, LLC v. Marina Coast Water District*, Superior Court of California, County of Monterey, Case Number 18CV000765, dated 8/20/2019, the Honorable Susan J. Matcham stated that "Tier 2 customers subsidize Tier 1 customers by paying far more than their fair share. Consequently, the 2018 Rates violate Proposition 218." The court's final disposition/ruling states that: "The court holds that MCWD's 2014 and 2018 Rates are invalid because they violate Proposition 218."

We appreciate the opportunity to comment and provide input on this draft GSP. Should any questions arise please feel free to contact me.

Sincerely,

MLerch

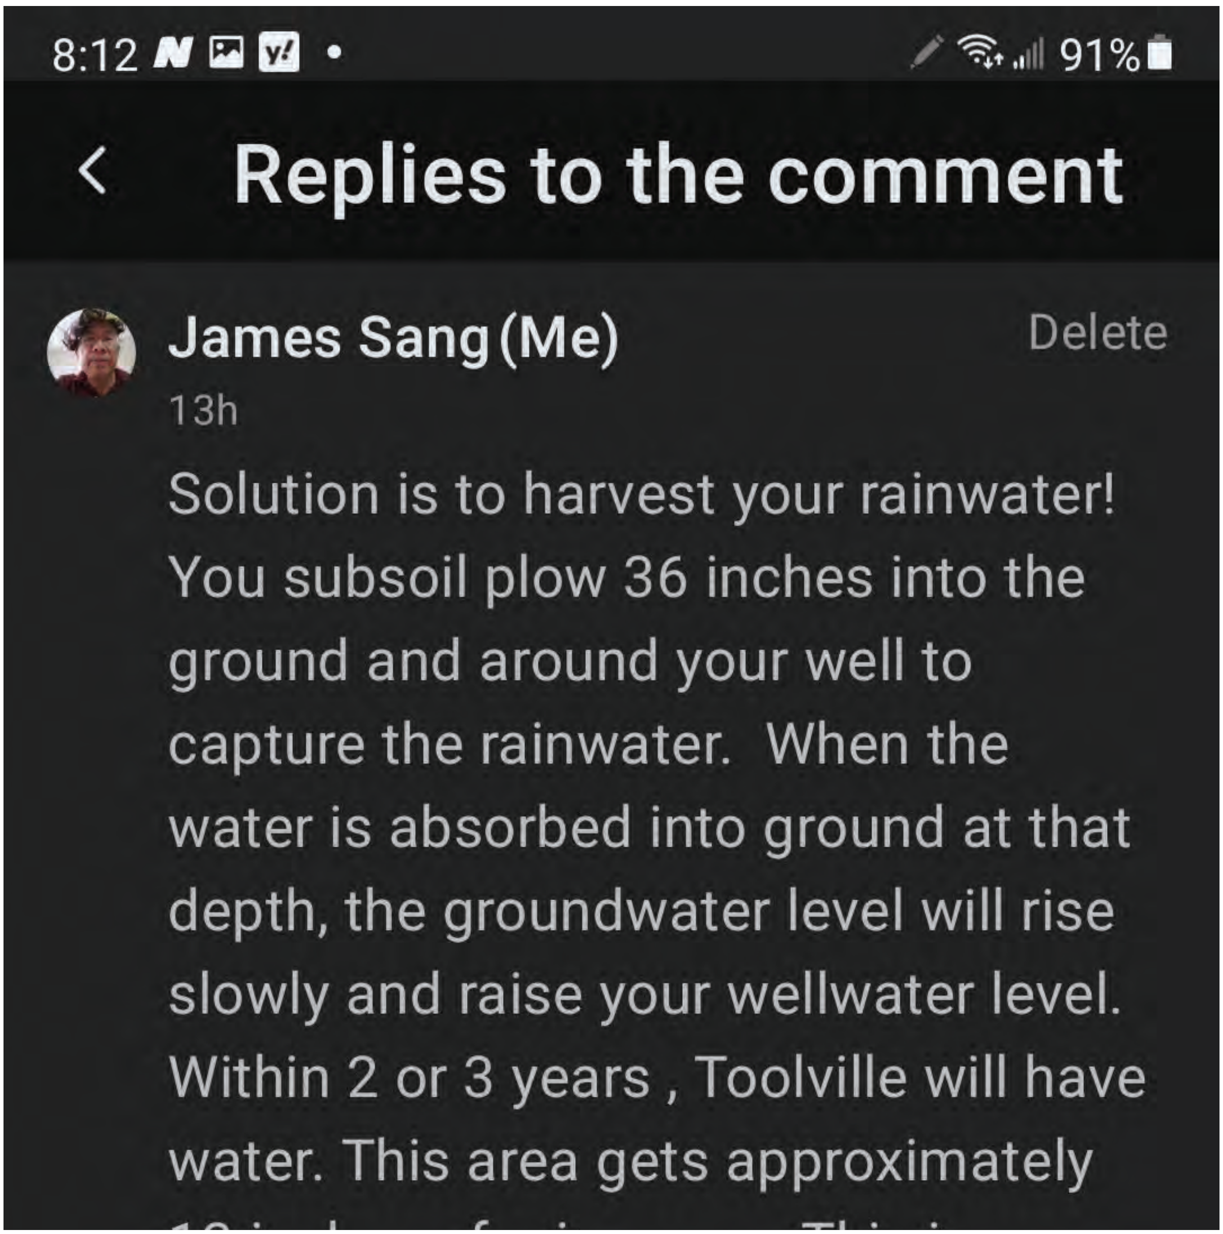
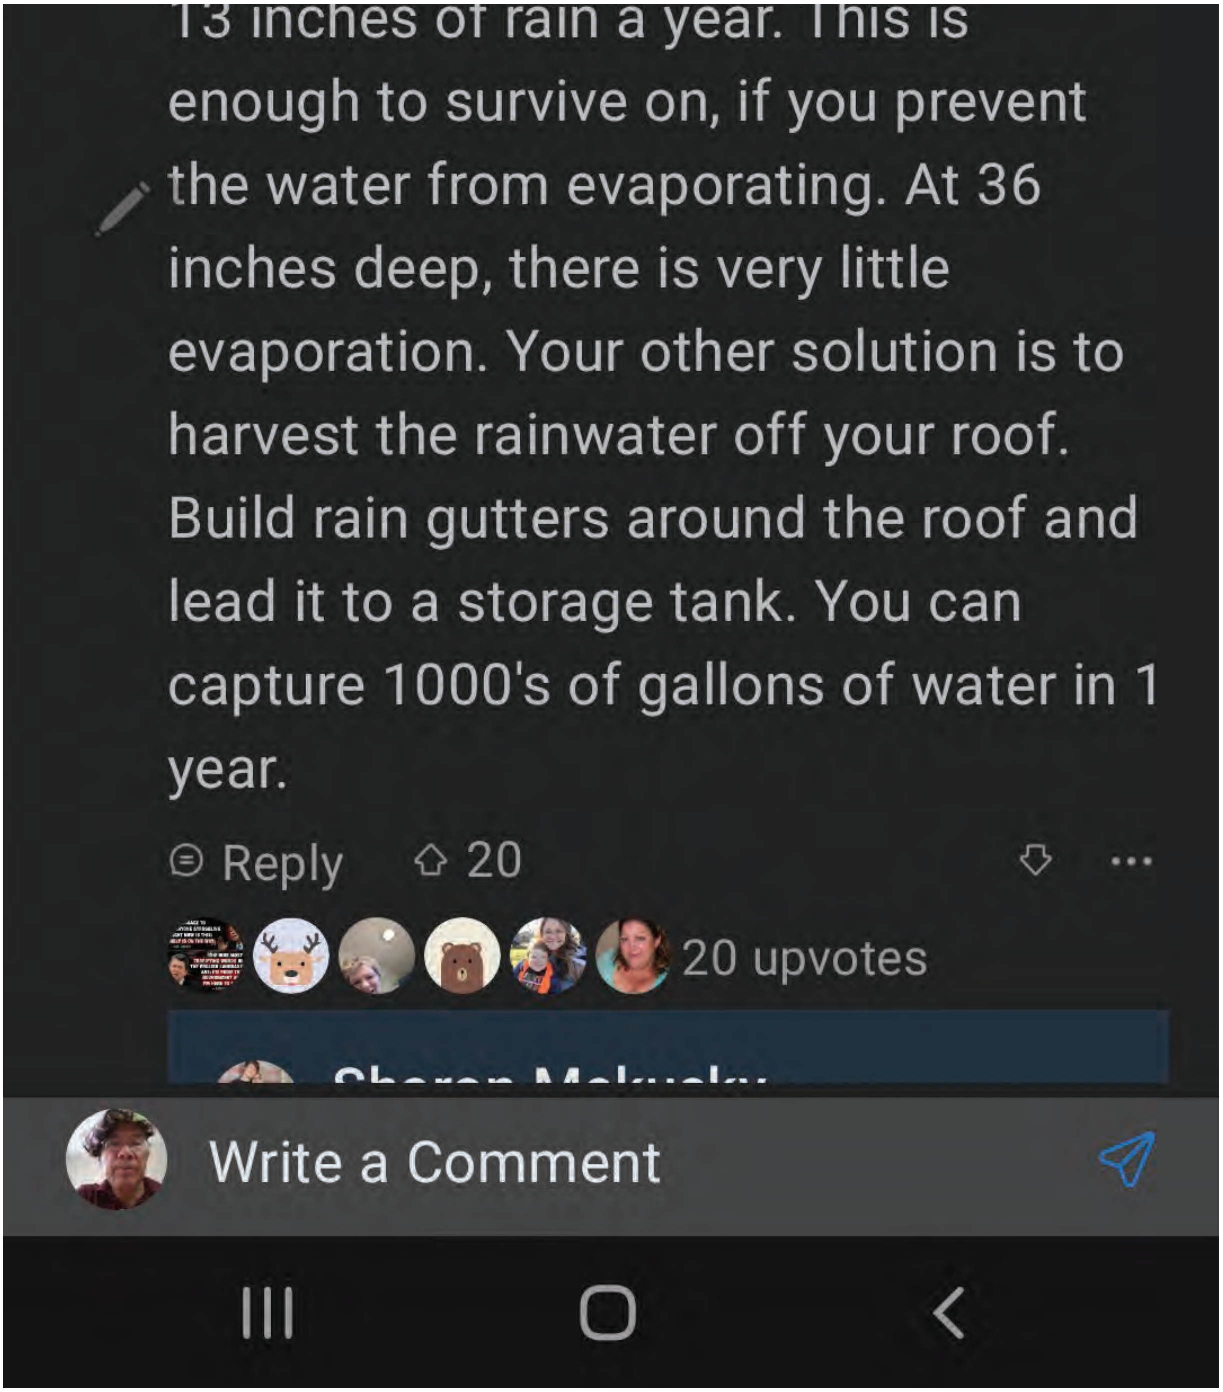
Subject:





Hello All,

These are the solutions that have been proposed to make the Monterey Sub-basin sustainable
1. They have proposed limiting pumping , fallowing land, buying property owners land. This is a terrible idea. This means less agricultural sales, lay off of employees, reducing the sales of all businesses in Monterey County. 2. Waste water recycling. This means upgrading existing CUS waster treatment plant. I like this idea even though it is super expensive. The capital cost is $28,635,000 and will only give us 232 acre feet of water per year. We should be able to recycle at least 70 percent of the water, which should help reduce the amount of groundwater pumping. This should help future growth in this area. A problem

that may be happening is that Cal Am may be forced to not take any more water from the Carmel River and they are a major supplier of water in this area. This has not been discussed. 3. Check dams are proposed on the tributaries in the Coral de Tierra area. These little dams are supposed to slow down the flow of stream water and allow it to be absorbed in the ground. The cost is $5,143,000 and give us 150 acre feet of water. I wonder if the designers of this project have considered that if the drought continues, we will get less and less rainfall and that even this small 150 acre feet of water will not be attainable, if climate change is real. With the increased CO2 production and the burning of our forest, which produces the water vapor to help precipitation. I would think that our rainfall will decrease. At least that has been what has been happening the last ten years or more. 4.They are proposing de-salination at a cost of $395,000,000 for an impressive addition of 15,000 acre feet water per year. Will we be able to afford this? I would like to know the arguments for and against this project. 5. They want to increase groundwater production from Upper Corral to the lower Corral at a cost of $13,275,000 for a benefit of 160 acre feet of water a year. Is this possible with the current lowering of our groundwater levels and will this source of water be for the long term? This project has not been discussed. 6. They want to introduce roof top rainwater capture and graywater reuse. The cost will be $100,000 for the classes and the benefit will be 5 acre feet of water per year for 75 households. I like roof top rain capture. If it rains 12 inches per year and you have a 1000 square foot area of roof, you can store 7,440 gallons a year. Currently our average rainfall is about 16 inches per year. In the Toro area, 39 percent of the wells have above average arsenic levels. Monterey County should notify these people and ask them to add a water filtration system to filter out the arsenic or go to roof top water harvesting and filter this water out for potable use. 7. Storm water recharge is a good idea. This diverts water off the streets, sidewalks, nonagricultural water and into swales. The cost is $200,000 to educate the people and can recharge 182 acre feet of water a year into swales, if it rains enough. Best practices require that this water be run over vegetation in order to detoxify it. If this is not done, you will be introducing street toxins into your groundwater and aquifers. There are other projects but they don't effect the Monterey sub basin.

The data on sustainable yield(amount of water coming in versus going out) for the Marina District(half of the Monterey sub-basin) and the Corral de Tierra(half of the Monterey sub-basin) area is not precise. An estimate is Marina District is minus 4000 acre feet of water a year and the Corral de Tierra is minus 3000 acre feet of water a year. None of these projects come close to bringing the Monterey sub-basin to sustainability except for maybe the de salination project and the benefits of that project will be spread to maybe the 180-400 sub-basin and the Eastside sub-basin . The completion of a de-salination project is years away and millions of dollars away. By that time we will all be THIRSTY!!

As I have mentioned before, the DWR's goal of water sustainability in the basins is incorrect! The goal should be to recharge and raise the water levels of each well. This is where the growers and the domestic users need to have their water. Do you really expect the growers and domestic users to drive their trucks to the area where the water is and fill their trucks and drive back?!! If we reach sustainability (water in equals water out) and some wells are still going dry, what will you do?? Build a pipe line here and build another pipeline there. This would be an endless project!!

We have a better chance of solving the water problems by using my idea of either subsoil plowing 2 or 3 feet or to build swales and trenches around the well heads in order to capture the rainwater every year. With the rainwater capture near the well head, we have a good chance of raising the well water levels, raising the groundwater levels and raising the water aquifer levels. These projects may only last the rainiest months (November, December, January) or last the full rainy season(October, November, January, February, March). After this they can plow over this area and grow their produce. This subsoil plowing and trenching can be done on any land to make it more water sustainable . Domestic well users can also implement this project, but on a smaller scale. Remember 1 acre of subsoiled or trenched land at 12 inches of rainfall a year will capture 350,000 gallons of water!

Other issues: 1. The Marina District area has a lot of toxins in the old Fort Ord area. These should be remediated as soon as possible before any recharge can be done. Maybe Assemblyman Richard Rivas or Senator Anna Caballero can help. There are approximately 15 areas that have to be cleaned. 2. There is over 9,000 acre feet of water going into 180-400 sub-basin yearly from the Monterey sub-basin. This might be caused by severe pumping by growers in the 180-400 subbasin. 3. Any further construction in this area should have their rooftop water go into recycling. 4. $7,000,000 has been awarded to the 180-

400 sub-basin. I would like see some of that monies go to using the technique of subsoil plowing and swale building in the Salinas Valley 5. About arsenic poisoning, this is a class 1 carcinogen . If you have to much arsenic in your blood increase your folic acid intake to 400 mcg and you will urinate it out [Folic acid supplementation lowers blood arsenic by Gamble, etc.]

Thanks for reading, any questions , please ask

SUBJECT: Comments on Monterey Subbasin Public Draft GSP Chapter 6

Dear Mr. Breen, Ms. Gardner, and Mr. Williams:

This letter is submitted on behalf of California American Water and provides comments on Chapter 6 (Water Budget) for the Public Draft Monterey Subbasin GSP Chapter 6 released on September 3, 2021. It also includes a brief review of how previous comments by the Hydrogeologic Working Group (HWG) on Monterey Subbasin GSP Chapters 4 (HCM) and 5 (Groundwater Conditions), which are attached to this comment letter, were not addressed in the recently released Public Review Draft versions of these chapters. Detailed comments are provided along with a summary of the main comments.

DETAILED COMMENTS

Specific comments are organized by subsection with page numbers referenced below.

Section 6.1 (Water Budget Method)

- The GSP states that the water budget information is based on use of a groundwater flow model developed for the subbasin (p. 6-8). **Comment: The model documentation (Appendix 6B) was not provided for review; thus, it is not possible to provide complete comments on the water balance without being able to review documentation for the model used to produce the water balance. Without the supporting documentation, stakeholders and the public are not able to adequately comment on the relevant issues.**

- The GSP states that a soil moisture budget (SMB) accounting model is used to estimate groundwater recharge (p. 6-10). **Comment: While Appendix 6-A provides some tables with output data from the SMB, no model documentation is provided. Thus, it is not possible to provide complete comments on the water balance without being able to review documentation for the SMB model used to**

provide key input to the groundwater model and water balance. Without the supporting documentation, stakeholders and the public are not able to adequately comment on the relevant issues.

- The GSP states, "As discussed in Appendix 6B, the MBGWFM has been calibrated against 30,354 historical water level measurements to achieve normalized calibration error statistics of less than 2% and thus adequately represents the historical conditions of the Basin. Therefore, it is appropriate to use the MBGWFM to estimate water budgets for the Monterey Subbasin." (p. 6-10). **Comment: Appendix 6B was not provided for review. While good calibration to water levels is important, it does not in and of itself validate use of the model for producing a valid water balance. Other key considerations include the fact that simulated water levels and subsurface inflows/outflows can be highly variable depending on boundary conditions. Thus, various combinations of recharge, discharge, aquifer parameters, and boundary conditions can produce similarly good model calibrations to water levels (i.e., models are non-unique). For example, a groundwater model with less vertical recharge could produce a good calibration to groundwater levels with a different set of aquifer parameters and/or boundary conditions. Therefore, additional justification is needed for use of the model for water balance output, such as comparison to adjacent subbasin water balances and the amount of vertical recharge (e.g., precipitation recharge, excess irrigation recharge) per acre. For example, the 180/400-Foot Aquifer Subbasin historical water budget has vertical recharge amounting to 0.22 ft/acre compared to the Monterey Subbasin historical water budget with vertical recharge of 0.33 ft/acre, or 50% greater vertical recharge than the immediately adjacent 180/400-Foot Aquifer Subbasin.**

- The GSP states, "To quantify all required water budget components as specified in the GSP Emergency Regulations (CCR § 354.18(b)), this GSP presents results from both the SMB for the land surface system and the MBGWFM for the groundwater system." (p. 6-11). **Comment: The GSP Emergency Regulations (CCR § 354.18(b.1)) require, "Total surface water entering and leaving a basin by water source type." A surface water budget is not provided in Chapter 6; this would include total streamflow and any imported water entering and leaving the Monterey Subbasin.**

<u>Section 6.2 (Water Budget Components)</u>

- The GSP states that inter-basin cross-boundary flows (e.g., between the Monterey Subbasin and the 180/400 Aquifer Subbasin) are based on model general head boundary conditions (p. 6-15). **Comment: The details of the general head conditions used (i.e., heads, conductance) are not provided and cannot be reviewed. Presumably such details would be provided in the Model Documentation in Appendix 6B if it were made available for public review.**

<u>Section 6.4 (Historical and Current Water Budget)</u>

- GSP Table 6-1 provides historical and current groundwater water budget results (p. 6-20). **Comment: The historical and current Monterey Subbasin water budgets show net subsurface outflows of 12,265 to 12,565 AFY to the 180/400-Foot Aquifer Subbasin. Review of the DWR-approved GSP for the 180/400-Foot Aquifer Subbasin shows historical and current water balance net subsurface**

inflows from the Monterey Subbasin of 3,000 AFY. Thus, there is a large discrepancy between the two GSPs regarding subsurface cross-boundary flows. If the Monterey Subbasin GSP cross-boundary flows are correct, the difference between inflows and outflows for the historical groundwater budget for the 180/400-Foot Aquifer Subbasin GSP changes from -12,900 AFY to -3,635 AFY, which has significant implications for the 180/400-Foot Aquifer Subbasin GSP. In general, this uncertainty in cross-boundary flows also points out that subbasin sustainability should be based (primarily) on balancing the vertical components of recharge and discharge. This eliminates the uncertainty regarding cross-boundary flows (and associated dependency) in evaluating projects/management actions needed to achieve sustainability.

- A footnote to Table 6-1 states, "All seawater inflows from the ocean are presumed to leave the Monterey Subbasin across the 180/400 Foot Aquifer Subbasin boundary, as evidenced by no observed expansion of the seawater intrusion front in the Monterey Subbasin over the historical time period." (p. 6-20). This issue is also discussed in the first bullet at the top of page 6-23, and first bullet at the top of page 6-24. **Comment: Review of seawater intrusion maps prepared by MCWRA indicates this statement/conclusion is not correct – the seawater intrusion front in Monterey Subbasin has expanded over the historical time period.**

- GSP Figure 6-4 (p. 6-21) indicates subsurface flow occurs from the Corral de Tierra Area to the Marina Ord Area. **Comment: Review of topography and studies by others (e.g., Geosyntec, 2007) indicates essentially no flow between the two Areas, but rather subsurface flow from the Corral de Tierra Area strictly to the 180-400 Foot Aquifer Subbasin. The water balance for Marina-Ord Area assumes such subsurface inflow amounts to 1,544 AFY, but this is likely not the case.**

- The GSP states that outflows to the ocean occur from the Dune Sand Aquifer (p. 6-22). **Comment: The HCM and groundwater elevation contour maps indicate that the Dune Sand Aquifer and 180-Foot Aquifer merge inland of the coast where the FO-SVA aquitard pinches out and the combined groundwater flow moves inland. The GSP presents no evidence of outflow to the ocean.**

- The GSP notes that estimated net annual inflows/outflows between the Monterey Subbasin and the Seaside Subbasin are consistent with the estimates from the Seaside Basin Groundwater Flow Model. However, this same statement of consistency is not made by the GSP for estimated net annual inflows/outflows between the Monterey Subbasin and the 180/400 Foot Aquifer Subbasin. **Comment: As noted above, there is a major discrepancy between the 3,000 AFY of net inflow to the 180/400 Foot Aquifer Subbasin from the Monterey Subbasin estimated in the 180/400 Foot Aquifer Subbasin GSP versus the 12,365 AFY of net inflow to the 180/400 Foot Aquifer Subbasin estimated in the Monterey Subbasin GSP.**

- The GSP notes that the Dune Sand Aquifer has seaward gradients that result in 534 AFY of net outflow to the ocean (p. 6-23). **Comment: The groundwater elevation contour maps presented in Chapter 5 do not include data points near the coast and provide no evidence of outflow to the ocean. In fact, other data indicate there is no outflow to the ocean from the Dune Sand Aquifer as described above.**

- The GSP states that groundwater elevations in the 180/400 Foot Aquifer Subbasin are 40 feet below mean sea level (MSL) in the 180 and 400-Foot Aquifers and 100 feet below MSL in the Deep Aquifer

(p. 6-24). **Comment: It should also be noted here that groundwater elevations in the Monterey Subbasin are 20 to 30 feet below MSL in the 180 and 400-Foot Aquifers and 50 to 70 feet below MSL in the Deep Aquifer.**

- Figure 6-5 (p. 6-27) shows an area of seawater intrusion in Monterey Subbasin with arrows showing groundwater flow directions in this area. The text describes these arrows as, "…the general direction of presumed freshwater and seawater cross-boundary flows…" (p. 6-28). The GSP also states, "…it is difficult to predict if seawater inflows from the ocean will continue to pass through the Monterey Subbasin into the 180/400 Foot Aquifer subbasin as they did during the historical period." (p. 6-42). **Comment: The area of seawater intrusion does not match the sea water intrusion maps prepared by MCWRA and does not distinguish seawater intrusion in the 180-Foot Aquifer vs. 400-Foot Aquifer as done by MCWRA. In addition, the groundwater flow direction arrows within the zone of seawater intrusion are incorrect and do not correlate with the groundwater elevation contours included on the map, which indicate a portion of the groundwater within the seawater intrusion zone flowing towards the middle inland portion of Monterey Subbasin. It is not clear why the groundwater flow directions shown are based on "presumed" directions rather than the flow arrows that would be derived based on actual groundwater elevation contour lines shown on the figure.**

- The GSP states, "…pumping in the Corral de Tierra Area is estimated using the known data, and may be missing a significant amount of pumping." (p. 6-33). **Comment: If a significant amount of pumping is not accounted for in the Corral de Tierra Area, then subsurface outflow is significantly overestimated.**

<u>**Section 6.5 (Projected Water Budget)**</u>

- Projected water demands for the MCWD service area are estimated to increase from 3,367 to 8,314 AFY, and it is assumed that increased pumping would be divided evenly between the 180 and 400 Foot Aquifers and the Deep Aquifer based on historical MCWD operations (pp. 6-37 and 6-38). **Comment: Given the evolution of MCWD pumping distribution between the Deep Aquifer and shallower aquifers to the point where Deep Aquifer pumping has apparently increased to become more than two-thirds of total MCWD pumping in recent years, it is apparent that the 180 and 400 Foot Aquifers cannot accommodate the proposed future pumping increases stated in the GSP. The future model scenario should assign all future increases in pumping to the Deep Aquifer. This pumping distribution will likely have a major effect on future scenario model results.**

- The GSP states that model boundary conditions used in future scenarios include: minimum thresholds (MT), measurable objectives (MO), and seawater intrusion protective boundary conditions (p. 6-38). **Comment: The seawater intrusion protective boundary conditions are not defined in terms of what they are or how they were derived, or how likely they are to occur. Since they are not provided in GSPs for adjacent subbasins as likely to occur, they do not seem appropriate to use.**

- The GSP states that for the MT Boundary Conditions in the projected model scenario run, "Groundwater levels in RMS wells located near the Monterey Subbasin are raised from 2018 model predicted values to water level MTs established in the 180/400 Foot Aquifer GSP…" (p. 6-38). **Comment: Review of water level data from MCWRA indicates that 2015 to 2016 water levels**

were generally lower than 2018 water levels. The 180/400-Foot Aquifer Subbasin GSP set MTs one foot above 2015 water level elevations. Thus, it is not clear why model-predicted 2018 water levels in boundary condition areas would need to be raised to be at MT levels established in the 180/400-Foot Aquifer Subbasin unless model-predicted groundwater elevations for 2018 were substantially lower than observed values. If model-predicted values are substantially lower than observed values in boundary condition areas, the model would likely significantly overestimate groundwater outflow from the Monterey Subbasin to the 180/400-Foot Aquifer Subbasin.

- The GSP states that seawater intrusion protective elevations are, "…consistent with the MTs for seawater intrusion established in the 180/400 Foot Aquifer GSP." (p. 6-39). **Comment: Based on this statement, it is not clear how seawater intrusion protective elevations differ from MT elevations. Several figures in the GSP suggest seawater intrusion protective elevations are much higher than MT elevations.**

- The GSP Project Scenario calls for increased use of recycled water from 600 AFY in 2023 to 5,495 AFY in 2040, with total demand in 2040 and beyond of 10,955 AFY. **Comment: This Project scenario assumes that recycled water can provide 50% of total water demand for MCWD, which is likely unrealistic. In addition, other documents (MCWD Urban Water Master Plan, MCWD Water Supply Master Plan) indicate future recycled water use would be limited to no more than 1,500 AFY.**

- The GSP states, "…the projected water budget results indicate that the climate scenarios have a much smaller impact on changes in storage and groundwater levels within the subbasin than the identified boundary conditions." (p. 6-43). **Comment: While this statement may be true relative to horizontal groundwater flows, it is not true with regard to vertical groundwater recharge that increases substantially (about 10 to 20%) under future climate change scenarios. Additional projected model runs should be made using historical groundwater recharge amounts due to the significant uncertainty in future groundwater recharge increases.**

- GSP Table 6-5 (Comparison of Projected Water Budget Results Under "No Project" Scenarios with Variable Boundary Conditions and 2030 Climate Condition, Marina-Ord Area WBZ) shows 8,767 AFY of groundwater pumping versus 6,823 AFY of total groundwater recharge (p. 6-45). **Comment: Under these scenarios groundwater pumping exceeds groundwater recharge by approximately 2,000 AFY and is not sustainable.**

- The GSP states, "…ocean inflows into the basin also decrease as water levels at this boundary increase from MTs, to MOs, and to SWI protective elevations…However, there is little reduction in net ocean inflows between the historical water budget and the projected baseline water budgets under MT boundary conditions or MO boundary conditions." (p. 6-48). **Comment: This statement would seem to indicate that ocean inflows are driven by Monterey Subbasin groundwater elevations.**

- The GSP states, "…projected water budgets also indicate that substantial groundwater outflows from Monterey Subbasin continue to occur into the 180/400-Foot Aquifer Subbasin under MT and MO boundary condition scenarios." **Comment: It should be determined how much of this groundwater outflow across Subbasin boundaries is due to sea level rise.**

- With respect to the Marina-Ord Area, the GSP states, "…these projected water budget results indicate that this management area will not be in overdraft if adjacent basins are managed sustainably and SMCs are achieved." (p. 6-50). **Comment: Given that pumping exceeds recharge by 2,000 AFY in in the Marina-Ord Area per Table 6-5, it is not clear how this Area can be considered to not be in overdraft under projected future conditions.**

- The GSP states, "…it is difficult to predict if…changes in boundary conditions and increased extraction in the subbasin could cause saline groundwater from the 180/400 Foot Aquifer subbasin or ocean to flow further inland within the Monterey subbasin. It is noted that MCWD has significant operational flexibility regarding rates of extraction from its wells and could potentially modify the location and depth at which groundwater is extracted to limit such impacts." (p. 6-50 to 6-51). **Comment: The groundwater model should be able to provide some indication of the potential for saline water from the ocean to flow further inland within the Monterey Subbasin. As discussed in other comments, MCWD does not appear to have operational flexibility on depth of extraction and additional pumping is likely to occur from the Deep Aquifer.**

- In reference to Figure 6-8, the GSP states, "This figure indicates that variable climate conditions have limited impacts on projected water levels in RMS wells relative to boundary condition scenarios." (p. 6-51). **Comment: This figure and the associated statement here are misleading with regard to the impacts of variable climate conditions assumed in the future scenario. The future climate change assumptions result in an increase in groundwater recharge ranging from 10 to 20%, which is highly uncertain. A better approach would be to assume groundwater recharge in the future will be similar to historical groundwater recharge. The assumption of increased future groundwater recharge may exacerbate overdraft that is already predicted to occur even with the assumed increased in groundwater recharge (see Table 6-5 where groundwater pumping exceeds future groundwater recharge by approximately 2,000 AFY).**

- The GSP states, "…these results suggest that projects and/or management actions may be required to consistently maintain water levels above MTs and to achieve MOs within the Marina-Ord Area unless SWI protective boundary conditions are achieved in the adjacent subbasins." (p. 6-51). **Comment: The 180/400 Foot Aquifer Subbasin GSP is approved by DWR with the MO/MT included in the GSP. It is not reasonable to evaluate/assume boundary conditions could be at the apparently much higher "SWI protective boundary conditions". Thus, it should be assumed that projects/management actions will be required in Monterey Subbasin to maintain water levels above MTs and achieve MOs within the Marina-Ord Area.**

- GSP Figure 6-8 indicates that Monterey Subbasin does not meet its MT when using MT boundary conditions for adjacent basins and does not meet its MO when using MO boundary conditions for adjacent basins in future project model runs for "No Project" conditions (p. 6-52). **Comment: These results demonstrate that projects/management actions will be necessary to meet MT and MO in Monterey Subbasin. The GSP Project with water supply augmentation by recycled water of 5,500 AFY far exceeds any other current projections of available recycled water (less than 1,500 AFY in MCWD UWMP).**

Section 6.6 (Historical, Current, and Projected Overdraft and Sustainable Yield)

- The GSP presents three methods of calculating sustainable yield of the Marina-Ord Area (p. 6-59 to 6-60). **Comment: Two of the three methods are based on comparing historical and current overdraft to groundwater pumping during these time frames, with resulting sustainable yield ranging from 2,714 to 3,294 AFY, or an average of approximately 3,000 AFY. This estimate is likely reasonable given that historical and current pumping amounts ranging from 3,503 to 4,346 AFY have resulted in groundwater basin overdraft and seawater intrusion. The third method of calculating sustainable yield in the GSP erroneously concludes that the projected water budget results support an estimated sustainable yield of 9,870 AFY, which is three times the amount of groundwater pumping that has already resulted in overdraft and seawater intrusion. Furthermore, this sustainable yield estimate is on the order of 50% greater than total groundwater recharge. While the GSP claims a sustainable yield of up to 9,900 AFY, it is clear from historical and current data that the sustainable yield of the Marina-Ord Area is likely no greater than about 3,000 AFY.**

- The GSP states that under the "no project" scenario RMS well groundwater levels "…are generally higher than MTs during non-drought periods under all identified boundary conditions and climate scenarios…" and that RMS well groundwater levels "…reach MOs if SWI protective boundary conditions are achieved in adjacent subbasins." (p. 6-60). **Comment: Review of Figure 6-7 indicates that groundwater levels are below the MTs more than 50% of the time after 2040 under MT boundary conditions, which is contrary to statements in the GSP. In addition, the DWR-approved 180/400 Foot Aquifer Subbasin GSP does not propose to achieve SWI protective groundwater levels; therefore, Monterey Subbasin RMS wells will not achieve proposed MOs.**

- The GSP states that the future projected sustainable yield ranges between 4,400 and 9,900 AFY if adjacent subbasins are managed sustainably and the 180/400 Foot Aquifer Subbasin reaches its SMCs (p. 6-60). **Comment: While there is some interdependence between subbasins that may impact the sustainability of adjacent subbasins, each subbasin in the Salinas Valley needs to be managed sustainably on its own to make the entire Salinas Valley sustainable. The 180/400 Foot Aquifer Subbasin GSP has been approved by DWR as doing its part to achieve sustainability. Seaside Basin has been adjudicated and is doing its part to be sustainable. Monterey Subbasin cannot rely on inflows from other subbasins (e.g., from Seaside Basin) nor simply blame other subbasins (e.g., the 180/400 Foot Aquifer Subbasin) for its own inability to reach sustainability. The Monterey Subbasin should do its part to become sustainable by balancing its vertical inflows and outflows (i.e., do not include adjacent subbasin inflows and outflows), including a sufficient allowance for outflows to the ocean to avoid seawater intrusion. Alternatively, Monterey Subbasin GSAs may choose to work with the adjacent 180/400 Foot Aquifer Subbasin to develop other means of achieving sustainability such as by implementing a coordinated groundwater extraction barrier to address seawater intrusion.**

- The GSP states with regard to the projected sustainable yield range for the Marina-Ord Area of 4,400 to 9,900 AFY, that that ability to conduct this amount of pumping without inducing seawater intrusion needs to be verified (p. 6-60). **Comment: It is not clear why pumping amounts in excess of historical pumping amounts that induced seawater intrusion would be proposed in a GSP without first**

verifying that they would not be expected to induce seawater intrusion. The groundwater model developed for the GSP should be applied to address this issue.

OTHER GENERAL COMMENTS

- The HWG previously reviewed Draft GSP Chapters 4 and 5 for the Monterey Subbasin, and provided comments dated April 5, 2021 (attached to this letter). While the HWG comments were acknowledged as being received by the GSA, the Public Draft versions of Chapters 4 and 5 include no significant changes to the text or figures related to the HWG comments. Furthermore, unlike responses provided to other comments submitted on the draft GSP chapters, there have been no responses to the HWG comments. Given that GSP development is a public process that is required include substantial public and stakeholder participation, and given that GSPs must be based on the best available science, the GSP should be revised to address the HWG's comments and the comments set forth herein. If the GSAs disagree with any of the subject comments, the GSAs should at the very least provide responses to the comments as they did for other comments.

- Chapter 6 of the GSP makes several references to details of the groundwater model being described in Appendix 6B; however, Appendix 6B had not been provided for review as of October 29, 2021, and comments were due on November 1, 2021. Given that the entire Chapter 6 is essentially based on the groundwater model developed for the GSP, the GSAs' failure to provide this model documentation precludes stakeholders and the public from being able to adequately review and comment on a foundational element of the entire GSP. The GSP cannot undergo adequate review until a sufficient review period is provided for Appendix 6B Model Documentation, and additional time should be provided to comment on Appendix 6B once it is provided to the public.

SUMMARY OF COMMENTS

The Monterey Subbasin GSP emphasizes in several places that subbasin sustainability is dependent on adjacent subbasins becoming sustainable. While there is some interdependence between subbasins that may impact the sustainability of adjacent subbasins, the GSAs in the Monterey Subbasin should focus on their role in making the Subbasin sustainable. This is best achieved by comparing groundwater recharge (just the vertical components of flow from the soil moisture balance, not including subsurface inflows form adjacent subbasins) in the Marina-Ord Area to groundwater pumping in the Marina-Ord Area. In addition, there needs to be excess groundwater recharge over and above total pumping for significant outflow to the ocean to prevent seawater intrusion.

A summary of several other major Chapter 6 comments includes:

- Groundwater model documentation is key to understanding the water balance, but is not included in available Public Draft GSP documents made available for review;
- Soil moisture budget accounting model documentation is key to understanding the water balance, but is not included in available Public Draft GSP documents made available for review;
- The surface water system water budget required under SGMA is not provided;
- There is a major inconsistency in estimated net subsurface inflow between the Monterey Subbasin and the 180/400 Foot Aquifer Subbasin presented in the GSPs for the two subbasins (i.e., 12,500 AFY vs. 3,000 AFY);

- The extent of seawater intrusion within the Monterey Subbasin has expanded over the historical period covered by the GSP, which is in contrast to statements/assumptions in the GSP;
- Some of the boundary conditions used in the groundwater model for future project scenarios are not realistic and are inconsistent with the 180/400 Foot Aquifer Subbasin GSP;
- The GSP Marina-Ord Area water balance indicates that increases in groundwater pumping for the future project scenario are not realistic and are not sustainable, because they exceed Marina-Ord Area groundwater recharge and do not allow for outflow to combat seawater intrusion;
- Future project scenarios should be more conservative and should not assume groundwater recharge will increase in the future by 10 to 20% due to climate change;
- Groundwater model results indicate that MTs and MOs will likely not be achieved in the Monterey Subbasin if realistic boundary conditions are applied; and
- The sustainable yield estimate of 4,400 to 9,900 AFY for the Marina-Ord Area is significantly overestimated, and will likely have detrimental impacts on adjacent subbasins (i.e., the Seaside Basin and the 180/400 Foot Aquifer Subbasin).

Thank you for the opportunity to provide these comments.

Sincerely,

LUHDORFF AND SCALMANINI

SUBJECT: HWG COMMENTS ON DRAFT MONTEREY SUBBASIN GROUNDWATER SUSTAINABILITY PLAN, CHAPTERS 4 AND 5

Dear Mr. Breen, Ms. Gardner, and Mr. Williams:

This letter provides the comments of the Hydrogeologic Working Group (HWG) on the Draft Monterey Subbasin Groundwater Sustainability Plan (GSP) Chapters 4 and 5. This letter provides both an Executive Summary highlighting some of our main comments, and a Detailed Comments section. It should be noted that the Executive Summary and Detailed Comments provided in this letter are not necessarily intended to be comprehensive, and additional comments may be provided at a later time.

EXECUTIVE SUMMARY

Our comments on the Draft Monterey Subbasin GSP Chapters 4 and 5 generally relate to the following items: description of geologic conditions, conclusions regarding groundwater conditions, preferential use of airborne electromagnetics (AEM) data over field data, and hydrogeologic interpretation of AEM data. Our high-level summary comments on Draft GSP chapters 4 and 5 are provided below, with a detailed comments section following this Executive Summary.

HWG summary comments on Chapters 4 and 5 are:

- The GSP presents a hydrogeologic conceptual model (HCM) with some inaccuracies based on invalid hydrogeologic interpretations of the AEM surface geophysics and other data that is not in agreement with available field data including boring logs, aquifer test, groundwater level, and groundwater quality data;
- The GSP does not utilize the most up-to-date hydrogeologic conceptual model for the northern Monterey Subbasin and southern 180/400 Aquifer Subbasin area in understanding the

hydrogeology of the area even the though the HWG conducted the most recent and extensive investigation of the hydrogeology specific to this area (e.g., HWG Technical Report, November 2017);

- Groundwater levels/quality and aquifer/aquitard continuity are mischaracterized in the northern Monterey Subbasin and southern 180/400 Aquifer Subbasin due to: inappropriate application of the Fort Ord Site Conceptual Model to this area; use of inaccurate hydrogeologic interpretations from AEM data; and lack of using all available field data and the most recent comprehensive hydrogeologic conceptual model of the area;
- The Dune Sand Aquifer (DSA) is not a Principal Aquifer and has been misclassified in the Monterey Subbasin GSP, and is in conflict with the 180/400 Foot Aquifer Subbasin GSP where the Dune Sand Aquifer is not classified as a Principal Aquifer;
- The inaccurate HCM analyses create conflicts with the 180/400-Foot Aquifer Subbasin GSP;
- While the HWG concur that achieving sustainability within the 180/400-Foot Aquifer Subbasin is important for achieving sustainability within Monterey Subbasin, the cause of depressed groundwater elevations and seawater intrusion in the Monterey Subbasin is mischaracterized as essentially being entirely due to pumping within the 180-/400-Foot Aquifer Subbasin and Seaside Subbasin; however, pumping from wells within Monterey Subbasin have played a major role in historical/current undesirable groundwater conditions and the Monterey Subbasin needs to do its part in achieving local and regional sustainability;
- The Monterey Subbasin GSP relies primarily on a study conducted by WRA Environmental (and by reference a study by Formation Environmental) in its discussion of groundwater dependent ecosystems (GDEs); however, there are many concerns about the methods/conclusions used in these studies to establish groundwater dependency of ecosystems that have been documented previously by HWG and supplemented by a recent study conducted by Geoscience/AECOM.

More specific and detailed comments on Monterey Subbasin Draft GSP chapters 4 and 5 are provided below.

DETAILED COMMENTS

Chapter 4 – Hydrogeologic Conceptual Model

1. The GSP states, “The geology described here is based on previously published scientific reports from investigations conducted by the USGS, State of California, other consulting firms, and academic institutions.”(Section 4.1.1, Geological and Structural Setting, p. 64).

HWG Comment: *We note that extensive field work conducted by the HWG between 2013 and 2018, including test slant well installation/testing, drilling of several borings and installation of an extensive monitoring well network, extensive data analyses covering the coastal southern 180/400-Foot Aquifer Subbasin and coastal northern Monterey Subbasin are documented in publicly available reports prepared by the HWG and posted on the Monterey Peninsula Water Supply Project (MPWSP) website (e.g., HWG,* *November 2017). These HWG documents incorporated data from previous studies by others (many of which are cited in the Monterey Subbasin GSP), and allowed for improved hydrogeologic interpretations by incorporating both existing and new field data collected by HWG. The Monterey Subbasin GSP ignores these HWG documents and makes geologic interpretations that are inconsistent with the most recent data that has been collected. Some of the specific inconsistencies are noted in other comments in this letter.*

2. The GSP mischaracterizes the Dune Sand Aquifer in multiple instances in Chapter 4. One example is the attempt to label the Dune Sand Aquifer as a "Principal Aquifer" (Section 4.2.1, Hydrogeology in the Marina-Ord Area, Table 4-1, page 79).

HWG Comment: *The Dune Sand Aquifer is not a Principal Aquifer in the subbasin. The Draft GSP prepared by City of Marina (2019) stated the Dune Sand Aquifer, "…is not commonly used for drinking water or agricultural irrigation". The Monterey County Water Resources Agency (MCWRA), which has studied and characterized the groundwater basin for many decades, does not consider the Dune Sand Aquifer as a principal aquifer (e.g., no seawater intrusion maps are prepared for the Dune Sand Aquifer by MCWRA). The 180/400-Foot Aquifer Subbasin GSP, which the MCWD GSA adopted and submitted to DWR, also does not classify the Dune Sand Aquifer as a Principal Aquifer. The Dune Sand Aquifer is not a Principal Aquifer due in part to its lack of capability for use in groundwater production (e.g., thin saturation, groundwater quality issues related to sea water intrusion and nitrates, etc.). In addition, the Hydrogeology section for the Corral de Tierra Area in Monterey Subbasin GSP Chapter 4 states that following about the upper 120 feet of sediments, "Several small domestic wells draw groundwater from these local alluvial aquifers, but these volumes of groundwater are minimal…Since this volume of groundwater is neither economic or significant, these shallow sediments are not considered a principal aquifer…Groundwater in these sediments is hydraulically connected to the small streams found in the area…" (page 111 of Chapter 4). This conclusion for the Corral de Tierra Area is inconsistent with designating the Dune Sand Aquifer, which cannot even claim to be tapped by "several small domestic wells", as a Principal Aquifer. As noted above, designation of the Dune Sand Aquifer as a Principal Aquifer is inconsistent with the 180/400-Foot Aquifer Subbasin GSP (where the Dune Sand Aquifer also is present), which specifically did not designate the Dune Sand Aquifer as a Principal Aquifer. It is also important to point out that the Dune Sand Aquifer, as defined in the Monterey Subbasin GSP, consists of two distinct aquifers – the coastal Dune Sand Aquifer that directly overlies the 180-Foot Aquifer and the perched/mounded Dune Sand Aquifer (known as the A-Aquifer in Fort Ord studies) that overlies the Fort-Ord Salinas Valley Aquitard (FO-SVA) clay layer (incorrectly referred to as Salinas Valley Aquitard in the Monterey Subbasin GSP). The coastal Dune Sand Aquifer is intruded with sea water, while the perched/mounded Dune Sand Aquifer is perched in areas, has thin saturation, is impacted by nitrates, and is not developed with production wells for any significant water supply uses.*

3. The GSP relies on old geologic cross-sections from 2001 (Section 4.2.1.1, Cross-Sections, pages 80-85).

HWG Comment: *The cited geologic cross-section references and Figures 4-9 through 4-12 do not utilize best available science and most recent borehole and geophysical logs for wells drilled in the area, nor do* *they utilize the most recent geologic cross-sections developed based on these data (see HWG, November 2017). This results in mischaracterization of hydrogeologic conditions for the GSP Plan Area. Geologic cross-sections that use the latest available data and include areas within the Monterey Subbasin are provided in previously published HWG documents (HWG, November 2017; HWG et al., February 2020).*

4. With regard to the Dune Sand Aquifer, the GSP states, "The aquifer is perched further away from the coast in areas where the SVA exists… " (Section 4.2.12, Principal Aquifers, page 86).

HWG Comment: *The HWG agrees with this GSP statement about the Dune Sand Aquifer being perched in areas where it is underlain by the SVA (more correctly referred to as the FO-SVA). However, perched aquifers should not be designated as Principal Aquifers as is being done in the Monterey Subbasin GSP.*

5. The GSP refers to an average saturated thickness of the Dune Sand Aquifer being approximately 50 feet (Section 4.2.12, Principal Aquifers, page 86).

HWG Comment: *As described above, there are two distinct aquifers being referred to collectively in the GSP as the Dune Sand Aquifer. While the coastal DSA may have a saturated thickness of 50 feet or more in some areas, the perched/mounded DSA has a saturated thickness considerably less than 50 feet.*

6. The GSP does not distinguish and describe the differences between the Salinas Valley Aquitard (SVA) and Fort-Ord Salinas Valley Aquitard (FO-SVA) and its significance to the perched/mounded aquifer (underlain by FO-SVA) versus the Dune Sand Aquifer and its equivalents (not underlain by FO-SVA) in many places in the document (Chapter 4).

HWG Comment: *It should be noted that the SVA and FO-SVA are not the same aquitard and FO-SVA occurs at a higher elevation; therefore, they should not be referred to as the same aquitard.*

7. The GSP shows a Conceptual Site Model diagram that was developed from Fort Ord studies, and implies that the Fort Ord Conceptual Site Model diagram applies throughout the Monterey Subbasin (Section 4.2.1.2, Principal Aquifers, Figure 4-13, p.87).

HWG Comment: *Recent studies completed by the HWG demonstrate that the Fort Ord Conceptual Site Model does not apply in the southern portion of the 180/400 Foot Aquifer Subbasin or the northern portion of the Monterey Subbasin. In particular, the concepts of an Intermediate 180-Foot Aquitard and lack of a 180/400 Foot Aquitard do not apply outside of Fort Ord. Work completed by HWG demonstrates that the 180-Foot Aquifer is one vertically continuous aquifer and that the 180/400 Foot Aquitard is present (HWG, November 2017).*

8. The GSP states that horizontal hydraulic conductivity in the DSA ranges from 0.14 to 120 feet/day (Section 4.2.1.2, Principal Aquifers, p.87).

HWG Comment: *It is important to distinguish the two major portions of what is referred to in the GSP as the DSA – coastal and perched/mounded. While the coastal DSA does have K values on the higher end of the cited range, perched/mounded portion of the DSA only has K values at the lower end of the cited range.*

9. The GSP makes general statements on hydrogeologic interpretations of AEM data, including outside of the GSP Plan area (Section 4.2.1.2, Principal Aquifers, p. 88).

HWG Comment: *It is not clear why the GSP is speculating on aquifer conditions outside of the Monterey GSP Plan Area based solely on AEM data, and without consideration of geologic and well data. The GSP also provides no demonstration/evidence of how these conclusions were reached. The HWG has previously provided extensive documentation of erroneous hydrogeologic interpretations of the AEM data (HWG, November 2017, January 2018, August 2018, January 2019, March 2019, and April 2019). The HWG April 2019 document clearly demonstrates with field data that the hydrogeologic interpretations of aquitard gaps from the AEM study are invalid. Furthermore, as described above, MPWSP monitoring well borehole logs demonstrate that areas of uncertain aquitard continuity identified by MCWRA (who did not have MPWSP monitoring well borehole data available to them at the time of their study) near the northern Monterey Subbasin boundary are no longer uncertain and clearly have significant aquitard material present. Furthermore, review of water level and water quality data for the MPWSP clearly demonstrate the presence and continuity of the 180/400-Foot Aquitard in this area.*

The Monterey Subbasin GSP does not describe the applicability of the concept of a sea water wedge (i.e., where sea water intrusion occurs, less saline water often overlies more saline water in a given aquifer) to explain the expected presence of less saline water overlying more saline water in some areas of the vertically continuous 180-Foot Aquifer. The presence of less saline water in the upper portion of an aquifer does not demonstrate the aquifer is not sea water intruded. Furthermore, given the standard of 500 mg/L chloride applied by MCWRA for defining the area of seawater intrusion, the AEM data collected in the area are not capable of distinguishing between a chloride concentration below the standard (e.g., 200 mg/L) from a chloride concentration above the standard (e.g., 600 mg/L) given inherent uncertainties in AEM data interpretation and the complicating variable of lithologic influences on AEM data.

10. The GSP states, "South of the City of Marina, in a portion of the former Fort Ord, the 180-Foot Aquifer is separated into an "upper" zone of sandy deposits with some gravel and a "lower" zone of gravel with sand and clay lenses; the two zones are separated by a thin clay layer (Ahtna Engineering, 2013). Data collected within the former Fort Ord show that significant head differences exist between the upper and lower ones of the 180-Foot Aquifer." (Section 4.2.1.2, Principal Aquifers, p. 91).

HWG Comment: *The HWG agrees that the area where this conceptual model applies is in a portion of former Fort Ord to the south of the City of Marina. However, the GSP implies this conceptual model (illustrated in Figure 4-13) applies throughout the GSP Plan Area, including north of Reservation Road, which is not correct as documented in work by HWG that is not referenced in this GSP (e.g., HWG, November 2017).*

11. The GSP discussion of the "Middle (180/400) Aquitard" suggests it is not present beneath the majority of the Marina-Ord Area, and implies this conceptual model applies throughout the Monterey Subbasin as illustrated by Figure 4-13 (Section 4.2.1.2, Principal Aquifers, p. 91).

HWG Comment: *As noted above with other aspects of the conceptual model presented in Figure 4-13, the concept that the 180/400 Foot Aquitard is not present in northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin is erroneous (see recent work by HWG not referenced in the GSP, as well as MCWD well logs). For example, HWG work demonstrates similar groundwater elevations in the upper and lower 180 Foot Aquifer (MW-6), and significantly different groundwater elevations and fluctuations in the 180 and 400 Foot Aquifers (multiple MPWSP monitoring wells).*

12. The GSP states, "The Lower 180-Foot Aquifer zone and the 400-Foot Aquifer in the vicinity of the City of Marina are functionally the same due to the missing Middle (180/400-Foot) Aquitard in this area." (Section 4.2.1.2, Principal Aquifers, p. 94).

HWG Comment: *As discussed above with other aspects of the Site Conceptual Model (Figure 4-13), this characterization does not apply to Northern Monterey Subbasin, contrary to what is stated/implied in the GSP.*

13. The GSP states, "Near the Monterey-Seaside subbasin boundary, a depression exists in the groundwater potentiometric surface of the 400-Foot Aquifer…These data suggest that a potential connection may exist between the 400-Foot Aquifer and the Deep Aquifer in this area." (Section 4.2.1.2, Principal Aquifers, p. 94.)

HWG Comment: *There is no geologic evidence provided in the GSP to support this statement. Preliminary review of geologic data (lithologic logs and Elogs) by HWG for MPWMD FO-10 and FO-11 indicate presence of sufficient thicknesses of clay layers to serve as aquitard layers between the 400-Foot and Deep Aquifers at this location.*

14. The GSP states, "As shown in Section 6 below, groundwater flow direction in the 400-Foot Aquifer is strongly influenced by groundwater pumping in the Salinas Valley Groundwater Basin, inland of the Monterey Subbasin." (Section 4.2.1.2, Principal Aquifers, p. 94)

HWG Comment: *A primary theme of this GSP here and elsewhere is that pumping in the 180/400 Foot Aquifer Subbasin is essentially solely responsible for seawater intrusion in the 180-Foot Aquifer and 400-Foot Aquifer within Monterey Subbasin, and for depressed Deep Aquifer groundwater elevations in the within Monterey Subbasin. However, the history of groundwater development in the Monterey Subbasin demonstrates how groundwater production wells developed for MCWD and Fort Ord resulted in seawater intrusion in the 180-Foot Aquifer and 400-Foot Aquifers in Monterey Subbasin (for example, see quote below from Harding ESE, 2001). In addition, Deep Aquifer groundwater elevations were fluctuating around sea level prior to pumping of Deep Aquifer wells by MCWD that dropped Deep Aquifer groundwater elevations well below sea level. Thus, groundwater pumping from wells screened in the 180-Foot, 400-Foot, and Deep Aquifers within Monterey Subbasin have played a significant role in historical/current seawater intrusion and depressed groundwater elevations within Monterey Subbasin.*

Harding ESE (2001) states: "Seawater intrusion beneath the city of Marina was observed soon after installing several production wells in the 180-Foot Aquifer (MCWD-1, the first city well, was installed in

1956). Subsequent seawater intrusion into this area was closely related to ground water withdrawal by the city of Marina and former Fort Ord. Deteriorating water quality forced the city of Marina to discontinue pumping most of its 180-Foot Aquifer wells by the late 1970's and install water-supply wells in the 400-foot (MCWD-8, -8a, and -9) and Deep Aquifers (MCWD-10, -11, and-12)."

15. The GSP states with respect to the Deep Aquitard (otherwise known as 400 Foot/Deep Aquitard), "There is no analysis available for its spatial occurrence or geologic composition." (Section 4.2.1.2, Principal Aquifers, p. 95).

HWG Comment: *The GSP could have conducted the "missing" analysis of the aquitard for the Monterey Subbasin given that several MCWD production wells (e.g., MWCW 10, 11, 12) and other wells (e.g., USGS deep nested monitoring well, agricultural wells) have available lithologic and geophysical logs. Such an analysis would demonstrate the presence of a 200 to 300 foot thick clay layer (i.e., 400/Deep Aquitard) between the 400-Foot Aquifer and uppermost Deep Aquifer Zone. The lack of seawater intrusion in the Deep Aquifer, which has groundwater elevations on the order of 50 to 100 feet below sea level in the northern Monterey Subbasin area and a strong vertically downward gradient from the 400-Foot Aquifer, combined with high salinity in the 400-Foot Aquifer within and surrounding the northern Monterey Subbasin also shows the strong integrity of the aquitard between the 400-Foot Aquifer and Deep Aquifer. T*he large difference in water levels between the 400-Foot Aquifer and Deep Aquifers also provides evidence of a thick/tight aquitard separating these aquifer zones.

16. The GSP describes the Reliz Fault as displaced the Monterey Formation, which is the base of the Deep Aquifer, shifted downward on the northeast side by 1,000 feet. It then states the fault does not appear to impede groundwater flow within the Dune Sand Aquifer, 180-Foot Aquifer, or 400-Foot Aquifers (Section 4.2.1.3, Structural Restrictions to Flow, p. 98).

HWG Comment: *The GSP does not comment on the possibility of the Reliz Fault altering groundwater flow within the Deep Aquifer.*

17. This section of the GSP begins, "This Section presents a general discussion of the natural fresh groundwater quality in the Marina-Ord Area, focusing on general geochemistry (Section 4.2.1.4, General Water Quality, p. 98).

HWG Comment: *Given the significance of historical and ongoing seawater intrusion in the Dune Sand Aquifer, 180-Foot Aquifer, and 400-Foot Aquifer in the Marina-Ord Area, it is unclear why this section would only describe the fresh water within the Marina-Ord Area.*

18. With regard to the Dune Sand Aquifer, the GSP states, "Groundwater in this aquifer is primarily fresh; minimal seawater intrusion has occurred in this aquifer (Section 4.2.1.4, General Water Quality, p. 98).

HWG Comment: *The coastal Dune Sand Aquifer is intruded by seawater, as demonstrated by monitoring wells at the MCWD office on Reservation Road (Staal, Gardner & Dunne, 1991 and 1992; Fugro West, 1996, 2001) and in the vicinity of the CEMEX site (HWG, November 2017).*

19. The GSP states, "The Dune Sand Aquifer contributes recharge to the 180-Foot Aquifer…" (Section 4.2.1.4, General Water Quality, p. 98).

HWG Comment: *It should be noted that this recharge from the Dune Sand Aquifer to the 180-Foot Aquifer is minimal (likely on the order of a few hundred acre-feet per year). This recharge has not stopped seawater intrusion from occurring in this area.*

Chapter 5 – Groundwater Conditions

1. The GSP notes data sources used in the GSP, which includes documents/data for Monterey Peninsula Landfill (Section 5.1.1, Data Sources, p. 6).

HWG Comment: *We note that Monterey Peninsula Landfill (MPL) is not located within Monterey Subbasin. In addition, if data from Monterey Peninsula Landfill are being used, why are data from MPWSP monitoring network not being used. Notably, later in Chapter 5, the GSP uses AEM data outside of Monterey Subbasin and within the area of MPWSP monitoring network data, yet there is no use of MPWSP data that contradicts the hydrogeologic interpretation of AEM data provided in the GSP.*

2. The GSP states that the Dune Sand Aquifer is a Principal Aquifer and that the 180-Foot Aquifer contains two distinct layers, known as the upper- and lower- 180-Foot Aquifer (Section 5.1.2.1, Marina-Ord Area, p.7).

HWG Comment: *The Dune Sand Aquifer should not be designated as a Principal Aquifer, and is in conflict with the 180/400 Foot Aquifer Subbasin GSP in this regard. Furthermore, the splitting of the 180-Foot Aquifer into two distinct aquifers only applies in the Fort Ord area, and does not apply in northern Monterey Subbasin (HWG, November 2017). While the entire thickness of the 180-Foot Aquifer is intruded by seawater near the coast and for a significant distance inland, the presence of less saline water within the upper portion of the 180-Foot Aquifer further inland is merely a function of the nature of seawater intrusion wedges, and not a function of the presence of an intermediate aquitard within the 180-Foot Aquifer in northern Monterey Subbasin.*

3. The GSP describes groundwater flow conditions in the 180-Foot Aquifer, and states, "…inflow from the Dune Sand Aquifer protects the upper 180-Foot Aquifer from seawater intrusion." (Section 5.1.2.1, Marina-Ord Area, p.8).

HWG Comment: *Any groundwater flow that may occur from the Perched/Mounded portion of the inland Dune Sand Aquifer to the underlying 180-Foot Aquifer has historically not prevented seawater* *intrusion from occurring within the 180-Foot Aquifer, which has been and remains heavily intruded with seawater. Any claims to the contrary, such as in this referenced statement from the Monterey Subbasin GSP, are incorrect. As noted above, there are not geologically distinct Upper and Lower 180 Foot Aquifers in northern Monterey Subbasin. The amount of recharge from the Dune Sand Aquifer to the 180-Foot Aquifer is small, as can easily be demonstrated by calculation of the amount of precipitation recharge in the Dune Sand Aquifer within the area west of the groundwater divide that has potential to recharge the 180-Foot Aquifer (e.g., on the order of a few hundred AFY, before subtracting Ford Ord remedial pumping). Furthermore, in order to dilute incoming seawater to a fresh water concentration, there would need to be over 30 times more fresh water than seawater in the mixing zone to create a net fresh water condition. Thus, a few hundred AFY of fresh water can effectively only dilute about 10 to 20 AFY of incoming seawater.*

4. The GSP states, "…the lower 180-Foot Aquifer is hydraulically connected to the 400-Foot Aquifer in the Marina-Ord Area due to the discontinuous nature of the 180/400-Foot Aquitard within this region…As such, groundwater elevation and gradients in the lower 180-Foot Aquifer are similar to those in the 400-Foot Aquifer in the Marina Ord Area of the Subbasin…" (Section 5.1.2.1, Marina-Ord Area, p.8).

HWG Comment: *This characterization of the discontinuous nature of the 180-400 Aquitard is not applicable to the northern portion of the Monterey Subbasin. Groundwater levels in the 180-Foot Aquifer and 400-Foot Aquifer are clearly different and distinct in the northern half of Monterey Subbasin and in the adjacent 180/400-Foot Aquifer Subbasin (HWG, November 2017). The Monterey Subbasin GSP does not demonstrate the similarity or difference in groundwater elevations to justify its characterization.*

5. Figures 5-1 and 5-5 show the western extent of the FO-SVA north of Monterey Subbasin as extending to MPWSP MW-3.

HWG Comment: *The extent of FO-SVA shown on the maps is outdated and also does not incorporate more recent data and analyses based on the MPWSP borehole/well data. We also note that groundwater elevation figures for all units except the Dune Sand Aquifer extend northward across the Monterey Subbasin/180-400 Foot Aquifer Subbasin boundary, even though many Dune Sand Aquifer well locations are available and shown on the figures for the MPWSP and MPL monitoring networks. In addition, there are several monitoring wells located at the MCWD District office headquarters and treatment plant on Reservation Road near the coast (Staal, Gardner & Dunne, 1991 and 1992; Fugro West, 1996 and 2001).*

6. In describing groundwater elevations in the 400-Foot Aquifer the GSP states, "A local groundwater depression exists just north of the Monterey-Seaside Subbasin boundary where a potential connection between the 400-Foot Aquifer and the Deep Aquifers may be located ." (Section 5.1.2.1, Marina-Ord Area, p.8).

HWG Comment: *The GSP provides no geologic evidence for a potential connection at this location between the two aquifers. The GSP only cites to HLA (2001) for cross-sections in this area, but other geologic cross-sections are available to consider from previous reports (e.g., HWG, 2017; Yates et.al., 2005). The location of this depression, which is more centrally located within Monterey Subbasin than described in the GSP text, is only about 1.5 miles south of MCWD Deep wells where a thick (i.e., 200 to 300 feet) aquitard exists between the 400 Foot Aquifer and Deep Aquifer.*

7. GSP Figures 5-1 and 5-5 (Groundwater Level Contours in the Dune Sand Aquifer – Fall 2017 and Spring 2018) show locations of MPWSP and MPL wells, but do not use the data to prepare groundwater level contours.

HWG Comment: *It is not clear why the GSP maps would show these MPWSP/MPL well locations but not use the data. We also note that geologic and borehole geophysical data from these wells are not used in developing geologic cross-sections or to develop an understanding of the geologic conditions for the HCM. This is particularly noteworthy in that the GSP Chapter 5 later uses hydrogeologic interpretations from the AEM data in lieu of actual borehole/well data to derive different conclusions regarding the HCM that are not supported by borehole/well data.*

8. GSP Figures 5-2 and 5-5 (Groundwater Level Contours in the 180-Foot Aquifer – Fall 2017 and Spring 2018) show locations of only three of the MPWSP wells (MW-6, MW-8, and MW-9), and do not use data from MW-8 and MW-9.

HWG Comment: *It is not clear why the GSP maps only show selected MPWSP well locations and do not use most of the data from the selected wells that are shown on the maps. We also note that geologic and borehole geophysical data from these wells are not used in developing geologic cross-sections or in developing an understanding of the geologic conditions underlying the HCM. This is particularly noteworthy in that the GSP Chapter 5 later uses hydrogeologic interpretations from the AEM data in lieu of actual borehole/well data to derive different conclusions regarding the HCM that are not supported by borehole/well data. We also note that groundwater is indicated to flow inland from the ocean to a pumping center in the north central portion of Monterey Subbasin.*

9. Figures 5-3 and 5-7 (Groundwater level Contours in the 400-Foot Aquifer – Fall 2017 and Spring 2018) show a +10 feet MSL contour as the shoreline in Marina Subbasin.

HWG Comment: *There is no well control to support this +10 feet MSL contour line, or even the zero contour line. We note that groundwater elevations in the 400-Foot Aquifer for MPWSP MW-3 (very close to the shoreline) ranged from 0 to -15 feet NAVD88 during this time period. We also note that groundwater is indicated to flow inland from the ocean to a depressed area in the south central portion of Monterey Subbasin. The Fall 2017 groundwater levels show that the pumping depression in the southern central area of Monterey Subbasin contributes to a broader depression that extends to the 180/400 Foot Aquifer Subbasin. Spring 2018 groundwater levels appear to indicate occurrence of a temporal groundwater divide around the MCWD well field.*

10. The GSP states, "…water levels in the Dune Sand Aquifer increase and decrease during extended wet and dry periods." This statement is apparently in reference to Figure 5-11: Representative Groundwater Elevation Hydrographs in the Dune Sand Aquifer (Section 5.1.3.1, Long-Term Groundwater Elevation Trends, Marina-Ord Area, p. 21).

HWG Comment: *The seven hydrographs shown in Figure 5-11 do not appear to respond to wet and dry periods. The only short-term response observed is around the year 2000 in the hydrograph for MW-OU2-05-A. This apparent stability of groundwater levels in the Perched/Mounded portion of the Dune Sand Aquifer is quite unlike the seasonal fluctuations that occur in response to pumping in the underlying aquifers, and further confirms that the DSA is undeveloped and essentially undevelopable as a water supply and therefore not a Principal Aquifer.*

11. The GSP states, "Groundwater elevations in the Lower 180-Foot Aquifer are generally equivalent to those observed in the 400-Foot Aquifer…" (Section 5.1.3.1, Long-Term Groundwater elevation Trends, 180-Foot Aquifer, Lower 180-Foot Aquifer, p. 21).

HWG Comment: *The GSP provides no evidence that groundwater elevations in the Lower 180-Foot Aquifer are equivalent to those in the 400-Foot Aquifer. In addition, no geologic evidence is provided that defines distinct Upper and Lower 180-Foot Aquifers in terms of a continuous intermediate aquifer throughout the Monterey Subbasin. MPWSP monitoring well MW-6 is a nested well cluster with separate wells in the upper and lower 180-Foot Aquifer and shows essentially identical groundwater elevations and fluctuations – it is located along Blanco Road on the border of the Monterey Subbasin with the 180/400-Foot Aquifer Subbasin.*

12. The GSP states that groundwater elevation data for MPWMD#FO-10 and MPWMD#FO-11 suggest, "…(1) these wells are screened within sediments that connect directly to the Deep Aquifers; or (2) leakage is occurring from the 400-Foot Aquifer into the Deep Aquifers in the vicinity of these wells." (Long-Term Groundwater Elevation Trends, 400-Foot Aquifer, p. 22).

HWG Comment: *Insufficient evidence is provided to make the stated conclusions; for example, no geologic evidence is provided to support these claims. In addition, more groundwater elevation data are needed to evaluate the gradient and flow direction in this portion of the aquifer. Preliminary review of geologic data (lithologic logs and Elogs) by HWG for MPWMD FO-10 and FO-11 indicate presence of sufficient thicknesses of clay layers to serve as aquitard layers between the 400-Foot and Deep Aquifers at this location.*

13. GSP Figure 5-15 shows groundwater hydrographs for Deep Aquifer wells near the Monterey Subbasin and 180/400-Foot Aquifer Subbasin boundary. Figure 5-16 shows Deep Aquifer groundwater pumping over time. In reference to the adjacent 180/400-Foot Aquifer Subbasin, the GSP states that, "…groundwater elevations in wells located near Cooper Road and Blanco Road have declined more than 5 ft/year over the past 15 years."

HWG Comment: *We note that the three wells in the 180/400-Foot Aquifer Subbasin have data through about 2020 and generally show fluctuating but overall stable groundwater elevations from about 2015 to 2020. Several of the MCWD wells within the Monterey Subbasin shown in the figure are lacking data from about 2017 to 2020, but the overall trend from available data appears to be declining groundwater elevations within Monterey Subbasin from 2015 to 2020. We note that Figure 5-16 shows significant increases in both agricultural and urban pumping from the Deep Aquifer after 2013, with urban pumping comprising approximately half of the total Deep Aquifer pumping over that time period. Figure 5-16 shows a doubling of urban pumping between 2013 and 2018, but no discussion/explanation of the sharp jump in urban pumping is provided in the text. Overall, the characterization of recent Deep Aquifer groundwater elevation trends between the two subbasins in the text appears to be inaccurate based on review of the figures.*

14. The GSP states, "These downward vertical gradients are caused by areal surface recharge, groundwater extraction from deeper aquifers, and laterally extensive aquitards, which exist in the Marina-Ord Area." (Section 5.1.4, Vertical Hydraulic Groundwater Gradients, pp. 31-32).

HWG Comment: *We note that the GSP references the presence of laterally extensive aquitards separating Principal Aquifers throughout Monterey Subbasin, a statement that we agree with, and yet the conceptual model described in GSP Chapters 4 and 5 provides for essentially no aquitard between the 180-Foot and 400-Foot Aquifers and a big hole in the thick aquitard between the 400-Foot Aquifer and Deep Aquifers.*

15. The GSP states that in the central Marina-Ord Area the groundwater elevations in the upper 180-Foot Aquifer are 70 feet lower than in the Dune Sand Aquifer (Section 5.1.4, Vertical Hydraulic Groundwater Gradients, p. 32).

HWG Comment: *This 70 foot difference in groundwater elevation almost certainly reflects the presence of perched aquifer conditions in the Dune Sand Aquifer at this location, which is why the HWG refers to the portion of the so-called Dune Sand Aquifer overlying the FO-SVA as the Perched/Mounded Aquifer. This observation also begs the question of why the Dune Sand Aquifer is being classified as a Principal Aquifer in this GSP, when much of it is a thinly saturated perched aquifer.*

16. The GSP states, "Within the Monterey Subbasin, seawater intrusion has been documented in the northern portion of the lower 180-Foot and 400-Foot Aquifers." (Section 5.3, Seawater Intrusion, p. 36).

HWG Comment: *As discussed other HWG comments in this letter, the designation of a geologically distinct lower 180-Foot Aquifer does not apply in the northern portion of the Monterey Subbasin. The entire thickness of the 180-Foot Aquifer is intruded at the coast and for some distance inland, with a seawater wedge having formed further inland (i.e., less saline water overlying more saline water due to density differences).*

17. The GSP describes data sources used in their analysis of seawater intrusion for the GSP, which include two airborne electromagnetic (AEM) surveys (Section 5.3.1, Seawater Intrusion, Data Sources, p. 36).

HWG Comment: *We note that the GSP utilizes an AEM profile entirely within the 180/400-Foot Aquifer Subbasin that passes through/near several MPWSP boreholes/wells, yet the GSP does not use the readily available MPWSP borehole/well data in its analysis. Furthermore, the HWG has conclusively demonstrated in previous documents (e.g., HWG, April 2019) that hydrogeologic interpretations derived from AEM data are flawed and inconsistent with borehole/well data.*

18. The GSP devotes several pages and two figures (5-26 and 5-27) to describing AEM surveys, primarily a profile entirely outside of the Monterey Subbasin (Section 5.3.1.2, Geophysical Data, pp. 36-38, 41-42, and 45-46).

HWG Comment: *It is not clear why the GSP relies so heavily on AEM data (primarily outside the Monterey Subbasin) in its discussion of seawater intrusion (and disregards borehole/well data for the same area) – especially given the flaws in the hydrogeologic and groundwater quality interpretations made using AEM data previously described in multiple HWG documents (e.g., January, March, April 2019). The hydrostratigraphy shown on the AEM profiles (Figures 5-26 and 5-27) is incorrect; particularly with regard to its depiction of aquitards (i.e., the presence of a continuous intermediate aquitard within the 180-Foot Aquifer and absence of a 180/400 Aquitard). In essence, the GSP is inappropriately trying to apply the Fort Ord hydrogeologic conceptual model (developed for a limited area south of Reservation Road) throughout the northern Monterey Subbasin and into the adjacent 180/400 Foot Aquifer Subbasin. Field borehole/well data demonstrate that application of the Fort Ord HCM to northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin is incorrect. There is no evidence/basis to support the stratigraphic interpretations in Figures 5-26 and 5-27 related to the presence (or absence) of aquitards between various aquifers. We note that there are no control points for the majority of the cross-section in Figure 5-26, yet the figure implies an abundance of fresh water. Field water quality data from MW-7M do not match that indicated on the profile. The two profiles are inconsistent; where control points exist with a TDS color coded legend the profiles are not shaded accordingly; however, where no control points exist to validate AEM water quality the profiles are shaded.*

19. In describing the purpose of the AEM surveys, the GSP states, "The studies' goal was to evaluate the understanding of the hydrostratigraphy in the study area and to interpret that distribution of groundwater quality indicated by available well data." (Section 5.3.1.2, Geophysical Data, p. 37).

HWG Comment: *While this statement references "available well data", it does not actually cite or use available well data. Rather, the GSP interpretations of hydrostratigraphy and seawater intrusion in this section are based primarily on interpretations of AEM data that are at odds with well data (see various HWG documents such as January 2019, March 2019, and April 2019).*

20. The GSP describes how AEM data (i.e. electrical resistivity) are dependent on, "…the amount of clay, the amount of water, and/or the salinity of the water…" (Section 5.3.1.2, Geophysical Data, p. 37).

HWG Comment: *While we agree with this statement, these facts also point out the high level of uncertainty associated with interpretation of AEM data in this coastal seawater intruded setting where multiple variables are impacting recorded AEM (resistivity) values. This allows for multiple non-unique interpretations of AEM data to be made in such settings, which creates more uncertainty in those hydrostratigraphic and groundwater quality interpretations. The GSP itself acknowledges that water quality interpretation is "difficult to discern" for a wide range of AEM resistivity values. The GSP does not acknowledge that geochemical interpretation of AEM resistivity values even outside of the cited large range are still subject to uncertainties related to variation in lithologic/saturation conditions.*

21. The GSP states, "The AEM surveys have found that high salinity groundwater as a result of seawater intrusion exists within the lower 180-Foot Aquifer and 400-Foot Aquifers of the Monterey Subbasin. This volume of high salinity groundwater is overlain by fresh groundwater in the Dune Sand and upper 180-Foot Aquifers. The results of the AEM study are consistent with water quality data collected within the Subbasin (EKI, 2019)." (Section 5.3.1.2, Geophysical Data, p. 38).

HWG Comment: *Both the AEM data and borehole/well data demonstrate that the coastal Dune Sand Aquifer and essentially the entire thickness of the 180-Foot Aquifer are seawater intruded from the ocean shoreline to approximately one mile inland. At that point, the coastal Dune Sand Aquifer begins to transition to the Perched/Mounded Aquifer that overlies of FO-SVA that is generally not seawater intruded because it is an elevated thinly saturated perched aquifer further inland, and the fully seawater intruded area of the 180-Foot Aquifer transitions to a seawater intrusion wedge with less saline water overlying more saline water due to density differences. While the results of the AEM survey may be consistent with the primarily Perched/Mounded Aquifer groundwater quality data cited in EKI (2019), the AEM survey based hydrostratigraphic and groundwater quality interpretations are inconsistent with the groundwater quality data collected for the MPWSP (e.g., HWG, April 2019) and key MCWD and Seaside Basin wells.*

22. The GSP presents an analysis (Figure 5-23) that demonstrates the definition of 500 mg/L chloride as the threshold for defining seawater intrusion is equivalent to a TDS of 1,000 mg/L. The GSP also cites the State of California upper Secondary Maximum Contaminant Level of 1,000 mg/L for TDS (Section 5.3.2, Defining Seawater Intrusion, p. 40).

HWG Comment: *We concur with the use of 500 mg/L chloride (although a good argument can be made for use of 250 mg/L chloride as a better indicator) and 1,000 mg/L TDS as an appropriate standards/thresholds for drinking water and seawater intrusion. We note that the AEM studies (study authors and study proponents) continue to argue for a drinking water and seawater intrusion threshold of 3,000 mg/L TDS, but this is at odds with GSP stated seawater intrusion and drinking water standards/thresholds of 500 mg/L and 1,000 mg/L TDS. Furthermore, due to the significant uncertainties in AEM groundwater quality interpretations, the AEM studies primarily attempt to differentiate* *groundwater above and below 3,000 mg/L TDS. The use of AEM data with a lower cutoff value (e.g., 1,000 mg/L TDS) results in even greater uncertainty in interpreted results than are achieved using the already uncertain AEM interpretations based on a cutoff of 3,000 mg/L TDS. We note that the GSP adopts a double standard by saying seawater intrusion has occurred when TDS exceeds 1,000 mg/L or chloride exceeds 500 mg/L in the Deep Aquifer, yet concentrations of 3,000 mg/L TDS and over 1,000 mg/L chloride represent low-TDS groundwater that is considered a source of drinking water supply in the AEM studies cited in the GSP.*

23. In reference to the AEM profiles shown in Figures 5-26 and 5-27, the GSP states, "TDS and AEM data shown on these cross-sections confirm that seawater intrusion in the Monterey Subbasin primarily exists in the lower 180-Foot Aquifer and 400-Foot Aquifer, whereas groundwater in the Dune Sand and upper 180-Foot Aquifers remains fresh." (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, p. 41).

HWG Comment: *While the statement refers to Monterey Subbasin, it should be noted that the Figure 5-26 is located entirely outside (north of) Monterey Subbasin, and Figure 5-27 contains very little data for the AEM profile within Monterey Subbasin. Furthermore, we have previously commented (in this letter and previous documents) on the flaws in the hydrostratigraphic and water quality interpretations shown on these AEM profiles (e.g., HWG, April 2019). Actual borehole/well data show the coastal Dune Sand Aquifer and entire thickness of the 180-Foot Aquifer are heavily intruded with seawater at the coast and for a significant distance inland. We recommend that AEM data only be used where results can be clearly validated with actual lithologic and water quality data. By not using this approach, the groundwater conditions are being misrepresented.*

24. In reference to the 180-Foot and 400-Foot Aquifers, the GSP states, "It appears that seawater intrusion in these two aquifers forms a unified intrusion wedge, due to the discontinuity of the 180/400-Foot Aquitard near the coast." (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, p. 41).

HWG Comment: *The HWG has previously demonstrated the flaws and inaccuracies in the hydrostratigraphic/water quality interpretations from AEM data inherent in this statement (i.e., absence of 180/400 Aquitard) (see HWG, April 2019).*

25. The GSP states, "Based on available TDS and AEM data, Figure 5-28 depicts the estimated extent of seawater intrusion within the Monterey Subbasin." (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, p. 41).

HWG Comment: *The area covered by Figure 5-28 does not include the AEM profile shown in Figure 5-26 and the AEM profile in Figure 5-27 provides very little data for the mapped area in Figure 5-28. Therefore, Figure 5-28 presumably is based essentially exclusively on TDS data. Furthermore, the area covered by Figure 5-28 has separate 180-Foot and 400-Foot Aquifers separated by an aquitard, so one map is mixing data from different aquifers and should be revised to be two separate figures as is done by the MCWRA.*

26. The GSP states, "…the 180-Foot Aquifer in the Subbasin is divided by an intermediate aquitard into an upper zone and a lower zone. There is no observed seawater intrusion in the upper portion of the 180-Foot Aquifer." (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, pp. 41-42).

HWG Comment: *As discussed previously in this letter, the area covered by Figure 5-28 does not have a continuous intermediate aquitard in the 180-Foot Aquifer, does have a 180/400-Foot Aquitard, and seawater intrusion is present in a significant zone along (and inland of) the ocean throughout the entire thickness of the 180-Foot Aquifer (see HWG, 2017; Staal, Gardner & Dunne, 1992; Fugro West 1996 and 2001).*

27. In reference to Figure 5-28, the GSP states, "The figure shows that depressed groundwater elevations in the 180/400 Foot Aquifer Subbasin are creating inland groundwater gradients that are contributing to seawater intrusion within the Monterey Subbasin." (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, pp. 41-42).

HWG Comment: *It should be noted that there are also depressed groundwater elevations from groundwater pumping within the Monterey Subbasin that are contributing to inland groundwater gradients that are contributing to seawater intrusion within the Monterey Subbasin. In fact, the groundwater elevation contour map provided in Figure 5-28 indicates flow lines from the ocean end in a groundwater depression within the Monterey Subbasin. Furthermore, much greater historical pumping from Fort Ord and MCWD wells within the Monterey Subbasin created seawater intrusion within the Monterey Subbasin. Once seawater intrusion occurs, it requires many decades of maintaining seaward gradients to flush saline water back out of the aquifers.*

28. GSP Figure 5-24 purports to show TDS concentrations and the extent of seawater intrusion in Monterey Subbasin (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, p. 43).

HWG Comment: *The dark blue zone in the Dune Sand Aquifer map extending approximately 0.5 miles inland from the shoreline suggests presence of fresh water coastal Dune Sand Aquifer, which is attributed to the 2018 AEM Survey report according to the map legend. The light blue zone that presumably attempts to define TDS concentrations below 1,000 mg/L includes a lobe that extends west of the FO-SVA extent that is not supported by any well data. On the contrary, available well data from the MCWD office site on Reservation Road for the Dune Sand Aquifer shows significant seawater intrusion has occurred in the area the AEM Survey report shown to be fresh water in the Dune Sand Aquifer along the coast (Staal, Gardner & Dunne, 1991 and 1992; Fugro West, 1996a and 1996b; Fugro West, 2001).*

29. The GSP states, "…seawater continues to flow across the area that is intruded towards the 180/400 Foot Aquifer Subbasin, while there is minimal migration of seawater intrusion to inland areas of the Monterey Subbasin. (Section 5.3.4, Historical Progression of Seawater Intrusion, p. 48.)

HWG Comment: *While the title of this GSP section refers to "Historical Progression of Seawater Intrusion", it fails to actually discuss the historical progress of seawater intrusion within Monterey Subbasin. As indicated in seawater intrusion maps prepared by MCWRA (Appendix 5B), a significant lobe of seawater intrusion into the 180-Foot Aquifer and 400-Foot Aquifer solely within Monterey Subbasin occurred south of Reservation Road in the 1970's and 1980's. This initial seawater intrusion into Monterey Subbasin occurred as a result of groundwater pumping from MCWD and Fort Ord wells screened in the 180-Foot Aquifer and 400-Foot Aquifer production zones, which were sequentially abandoned and moved inland and/or deeper as seawater intrusion moved inland in response to pumping of MCWD and Fort Ord production wells (Harding ESE, 2001). Most of the saline water that was induced to flow into Monterey Subbasin in the 1970s and 1980s still resides in Monterey Subbasin aquifers, and remains part of the overall area of seawater intrusion that exists today.*

30. Figure 5-29 of the GSP (Total Dissolved Solid Concentration Trends in the Lower 180-Foot, 400-Foot Aquifer) shows historical and recent TDS concentrations in various wells, including MCWD Wells MCWD-29 and MCWD-31. (Section 5.3.4, Historical Progression of Seawater Intrusion, p. 49).

HWG Comment: *Figure 5-29 indicates TDS concentrations of approximately 400 mg/L during 2019 in MCWD-29 and MCWD-31. Review of the 2019 AEM Survey Report Table 4-1 shows that AEM based TDS concentrations in the zone screened by these wells is estimated to be greater than 1,000 mg/L (about three times the field measured concentrations). Based on analysis (AEM data is a major data source of mapping sweater intrusion in the GSP) and relationships between chloride and TDS established in the GSP (e.g., chloride concentrations of 500 mg/L equate to TDS concentrations of approximately 1,000 mg/L), it seems that MCWD wells MCWD-29 and MCWD-31 should be included within the area of mapped seawater intrusion. In fact, this discrepancy demonstrates how interpretation of AEM data with regard to water quality can result in significant errors relative to field measured data. Interpreted AEM data has also been shown to significantly underpredict TDS/chloride concentrations (e.g., HWG, April 2019) is some areas.*

31. The GSP relies on a study conducted by WRA Environmental (2020) to conclude that 19.51 acres of aquatic and upland biological communities at six ponds are dependent upon groundwater (Section 5.7.1, Groundwater Dependent Ecosystems, Coastal Vernal Ponds within the City of Marina, p. 68).

HWG Comment: *We note that the five authors of the report by WRA Environmental are all biologists, with no apparent contribution from a hydrogeologist to help evaluate groundwater conditions and dependence of the plant communities on groundwater. The only investigation of groundwater in the report was digging a hole to 14 inches in depth to look for soil saturation; however, these field efforts are inadequate to determine groundwater conditions at the sites because there may be shallow fine-grained sediment layers supporting perched/saturated soils in the upper few feet of soil. The WRA report also cites the fact that their field efforts were conducted in June 2020, well after the end of the rainy season, and water was still observed in most of the ponds (implying it must be groundwater). However, review of monthly precipitation data for the 2019 and 2020 water years indicates the 2019 year was very wet (133% of normal) and the 2020 water year was wet (105% of normal). In addition, heavy rainfall* *occurred in March and April 2020 (about 6.5 inches or close to half the average annual rainfall) with smaller amounts of rainfall in May and June; therefore, it would be expected that surface runoff remained in the ponds with near surface saturation at the time of WRA's June 2020 site visits. We also note that the WRA Report relies on other studies such as Formation Environmental (April 2020) and the draft City of Marina GSA GSP (2020). The HWG has previously commented on these studies, and Geoscience/AECOM conducted the most recent study on the vernal pools (HWG, November 2019; Geoscience and AECOM, August 18, 2020). Summary Geoscience/AECOM comments on the Formation Environmental TM included: 1) very limited use of available groundwater data from MPWSP MW-4 and MW-7 to one point in time without considering entire record and impact of agricultural irrigation return flows in immediate vicinity; 2) relies solely on ET data to justify conclusion that Armstrong Ranch Ponds are groundwater dependent without consideration of alternative water sources such a seasonal surface water from rainfall; 3) failure to account for perched aquifer conditions underlying area; 4) failure to account for effects of urbanization surrounding six ponds in city of Marina that caused ponds to become primarily reliant of surface water runoff and leading to ponds becoming perennial. Furthermore, all six ponds in the Marina area are not hydraulically connected to the coastal Dune Sand Aquifer (thus, pumping from coastal Dune Sand Aquifer will not affect them); and all ponds received surface discharge from storm drains that empty into the ponds. Several ponds were found to have hardpan layers beneath them that limit percolation and likely account for WRA observations of shallow saturation. In addition, water quality data suggest that ponds are more influenced by stormwater runoff than groundwater from the perched aquifer system. Overall, it was found that the Formation Environmental study is fundamentally flawed , misrepresents potential impacts on ponds from pumping in the coastal Dune Sand Aquifer, and does not consider all available evidence concerned the nature of these pond resources and potential impacts to them from pumping. HWG comments on the City of Marina GSA Draft GSP state, "the fact that nearby GDEs are seasonally flooded and have a seasonal nature to them (and are associated with "a lens of less pervious soil") suggests a surface water source is most likely sustaining vegetation in these areas. The GSP evaluation to determine if potential GDEs are actual GDEs did not consider that shallow groundwater in these nearby potential GDE areas is saline or the likelihood that fresh surface water is the primary sustaining factor for these areas and (which means they are not GDEs)."*

32. We note that the City of Marina Draft GSP stated the following with regard to pumping from Marina Coast Water District Deep Aquifer wells, "The combined extraction from these wells was approximately 1,823 AFY in 2015, and is forecast to increase to 3,905 AFY by 2035…" (Section 3.1.8, page 3-17).

HWG Comment: *While the Monterey Subbasin GSP comments on the impacts of increasing pumping from the Deep Aquifer in the adjacent 180/400-Foot Aquifer Subbasin, it is silent on the issue of increased pumping from existing (and potential future new) MCWD Deep Aquifer wells. The cited MCWD Deep Aquifer pumping numbers represent a greater than doubling of the amount of current MCWD pumping from the Deep Aquifer, a pumping amount that already results in Deep Aquifer water levels within Monterey Subbasin on the order of 50-100 feet below sea level. Such increased pumping from the Deep Aquifer by MCWD and others is likely not sustainable.*

33. We note that the City of Marina Draft GSP stated, "In the Monterey Subbasin, groundwater demand from the Deep Aquifer by MCWD to supply the City of Marina is expected to increase….however, the increase is projected to be within MCWD's allocated pumping rights." (Section 3.3.10.4, page 3-69).

HWG Comment: *Regardless of the validity of allocated pumping rights (which is yet to be determined), it remains unclear if the proposed MCWD increase in pumping from the Deep Aquifer is sustainable. In addition, the increased pumping from the Deep Aquifer to the east to support agricultural expansion is based on overlying rights, not allocated (paper water) pumping rights, and are thereby presumably superior to MCWD rights.*

Monterey Subbasin GSP Comment Log (Prepared by SVBGSA)

1. In Comment 41 (dated 1/7/21) Tina Wang states, "…There is one thing we pointed out in that chapter, is the dune sand aquifer and the upper 180 foot aq is not SWI intruded, it is fresh."

HWG Comment: *As pointed out in our comments on GSP Chapters 4 and 5, the Fort Ord Site Conceptual Model (i.e., continuous intermediate aquitard within 180-Foot Aquifer and lack of a 180/400-Foot Aquitard) does not apply in northern Monterey Subbasin. Furthermore, available field data indicate that the Dune Sand Aquifer and upper portion of the 180-Foot Aquifer are seawater intruded (chloride greater than 500 mg/L) for a significant distance inland from the coast in the northern Monterey Subbasin and Southern 180/400-Foot Aquifer Subbasin. We also note that EKI's (and others) definition of fresh water in many previous documents related to the MPWSP has been TDS up to 3,000 mg/L; however, HWG have shown such levels of TDS also have greater than 1,000 mg/L chloride in the area, which is far in excess of the 500 mg/L standard applied by MCWRA for seawater intrusion. The Monterey Subbasin GSP uses AEM data outside of Monterey Subbasin (i.e., in southern 180/400-Foot Subbasin) to claim the presence of this so-called fresh water, yet actual field data show seawater intrusion has occurred at the coast and for a significant distance inland in this area (see HWG, 2017).*

2. In Comment 44 (dated 1/7/21) Derrik Williams responds to the commenter (Bob Jaques) that, "We have discussed the AEM data with some members of the blue ribbon panel…the didn't have too many concerns.'

HWG Comment: *If the commenter is referring to the Hydrogeologic Working Group, this statement by Derrik Williams is incorrect. The HWG has many concerns about the hydrogeologic interpretation of the AEM data and has documented our concerns in numerous documents (e.g., HWG, 2017; HWG, 2018; HWG, January 2019; HWG, March 2019; HWG, April 2019; HWG, June 2020).*

Sincerely,

The Hydrogeologic Working Group (Dennis Williams, Tim Durbin, Martin Feeney, Peter Leffler)

RE: Groundwater Sustainability Plan – Monterey Subbasin
Marina Coast Water District Groundwater Sustainability Agency
Salinas Valley Basin Groundwater Sustainability Agency

Dear Mr. Remleh Scherzinger:

The City of Seaside received a notice dated September 20, 2021 from the Marina Coast Water District Groundwater Sustainability Agency (MCWD GSA) that they had prepared a draft Groundwater Sustainability Plan for the Monterey Subbasin (the GSP) as required by the Sustainable Groundwater Management Act (SGMA). Staff reviewed the draft Groundwater Sustainability Plan, Monterey Subbasin prepared by EKI Water & Environment, Inc. for the Marina Coast Water District Groundwater Sustainability Agency and the Salinas Valley Basin Groundwater Sustainability Agency dated September 2021 (the GSP) download from the MCWD website on October 13, 2021 from the following link https://mcwd.org/gsa_gsp.html. The following comments are submitted for your consideration.

1. The City of Seaside requests to be included as stakeholder (page 28)
2. The City of Seaside is requests membership in the Technical Committee (page 8-10)
3. Since the Framework agreement between the MCWD GSA and the SVBGSA (the Agreement) appears to give MCWD additional jurisdiction within the City of Seaside city limits beyond the MCWD GSA boundary, the Agreement should be made available for review and comment by the City of Seaside (page 12).
4. The MCWD should clarify how the Water Augmentation Project would be implemented to ensure proposed development would not cause exceedances of groundwater extraction allocations (pages 6-57 and 9-31)
5. The GSP should clarify how the sustainable yield would be affected by the 180/400 & the Seaside Subbasins operated under conditions similar to current conditions or probable future conditions that do not meet MT or MO boundary conditions (page 6-59).
6. The MCWD should support the Seaside Watermaster to facilitate the development of alternative water for replenishing the Seaside Subbasin to ensure that the Seaside

Subbasin is able to achieve Protective Water Levels to mitigate seawater intrusion (page 9-13).

7. The GSP should clarify if Project R2, Regional Municipal Supply, is substantially different than the Regional Project as proposed by Cal Am. If not, why is "Further analysis and scoping ... needed to determine the exact location of the desalination plant, end uses, and desalination technology [9.4.2]"? If so, how are they different? (page 9-26)
8. In Section 9.4, the GSP should tabulate the scope of and capital costs for the proposed Seawater Extraction Barrier Project (page 9-26). The scope should clarify alternatives for discharging and/or reusing extracted brackish water (page 9-28).
9. It is assumed that additional investment is required to reimburse the capital expenditures and debt servicing incurred by MCWD for producing 600 AFY of recycled water. The MCWD should clarify what this investment is (page 9-58).
10. Since the GSP states that potable water could be delivered to Zone 2C by direct diversion and treatment from the Salinas River during certain months with some minor permit modifications, it should also be possible to deliver irrigation water through direct diversion. This should be explored and promoted as an alternative for providing irrigation water to supplement the more expensive treated water from Pure Water Monterey (i.e. $1,100/AF versus $1,600/AF, respectively) (page 9-22)
11. Section 10.7.1, "MCWD GSA Start-up Budget and Funding to Meet Costs," should be modified to include capital projects costs which are part of the costs for implementing the GSP over the next five years and should include an estimated cost to rate payers if no grant funding becomes available (page 10-16).

In addition, attached is a table of minor comments and requests for clarifications on the GSP. Please contact me at npatel@ci.seaside.ca.us or (831) 899-6884 if you require any further clarification on our comments.

Sincerely,

Nisha Patel
Public Works Director/ City Engineer

Review Comments
Marina Coast Water District GSA Groundwater Sustainability Plan

Page Label	Comments
12	Please add "the City of Seaside" to the definition of the Marina-Ord Management Area.
12	Since the Framework agreement between the MCWD GSA and the SVBGSA (the Agreement) appears to give MCWD additional jurisdiction within the City of Seaside city limits beyond the MCWD GSA boundary, the Agreement should be made available for review and comment by the City of Seaside.
28	Please confirm that the City of Seaside would be included in the stakeholder database.
55	If the "2020 UWMP anticipates that projected water demand within the entire District would be 9,584 AFY by 2040, including 2,974 AFY within the City of Marina and 6,610 AFY for the existing and future developments within the Ord Community," why is it shown as 9,300 AFY here?
145	The ordinate scales on the groundwater elevation graphs are too large to confirm if a linear trend line is best fit for determining trend lines. Please clarify why linear trend lines were selected to approximate groundwater elevations in the 400-ft aquifer.
149	Confusion in datum for groundwater elevations. Figure 5-12 states that it is both msl and NAVD88. These are not the same datum.
213	Why has the inflow from Seaside Basin increased by 45% from historic to current? Is this trend expected to continue?
215	Was annual well pumping determined from well meters (i.e. does it include non-revenue water or leakage)? If not, then that component of leakage should be omitted from the estimated recharge.
233	What does the following statement mean? "... fall within the middle of the range of projected boundary conditions."
235	Unclear. Is the assumption that the MT or MO Boundary conditions are achieved in the short term?
238	Why is well pumping under the "No Project" scenario shown as 8,767 AFY when the MCWD UWMP estimates that the demand would be 9,584 AFY. Applying the 5% leakage rate used in this GSP indicates future pumping should be 10,088 AFY. Please clarify.
243	Could groundwater extraction along the coast mitigate the inland flow of seawater? Could modeling this scenario help?
244	Should modeling be performed to predict scenarios under which MCWD alters pumping regime to minimize seawater intrusion?
245	What causes groundwater elevations to instantaneously increase by 2 feet under the no project condition?
245	How was the MO of approximately 7-ft increase determined?
245	How was the MT of 2-ft increase determined?
248	Is this correct? Outflow from the 180/400 Subbasin are affecting the Monterey Subbasin?
250	Note (c) is missing.
250	Table 6-5 (No Project Condition) shows outflow to 180/400 Subbasin at 3,849 AFY and 1,927 AFY for MT and MO boundary conditions, respectively. Table 6-8 (Project Condition) shows 6,833 AFY and 4,901 AFY respectively. This appears to indicate that the MT and MO boundary conditions to the 180/400 Subbasin are attained at significantly different times or are different for the "No Project" and "Project" scenarios. This appears to also be the case for inter-basin transfer to the Seaside Basin. Can this be better explained?
250	Table 6-5 (No Project) shows well pumping at 8,767 AFY for MT and MO boundary conditions. Table 6-8 (Project) shows 4,488 AFY for MT and MO boundary conditions. Does the model account for variability in pumping conditions since the Water Augmentation project would not come on-line for at least 6 years (see Fig. 9-6)? That is, what would cause and when would pumping exceed 4,488 AFY under the "Project" Conditions?
250	Do the future pumping rates shown in Table 6-8 account for leakage?
251	Are the increases in groundwater elevations shown here mostly attributed to actions performed, and MTs and MOs achieved, in adjacent subbasins?
252	It appears that this report is stating that if the adjacent subbasins are no operated sustainably, then the Monterey Subbasin could not be managed sustainably?
252	The groundwater levels appear to stabilize within the first 10 years due to assumed actions in adjacent subbasins. It could be important to consider the effects on water budget for scenarios where the adjacent subbasins are not operated under MT and MO boundary conditions.
253	It is unclear how the range of 4,400 to 9,900 AFY was determined? Above the report states that 2,714 AFY is the lower limit of the range and Table 6-5 suggests that 8,767 AFY is sustainable if MOs are achieved.
256	Is there a discontinuity in the modeling geometry at the interface of the Seaside Basin and MBGWFM? If so, how can this be rectified?
311	Based upon Table 6-4, it appears that sustainability goal can be achieved mostly by inter-basin coordination.
312	How will Seaside Watermaster Actions be supported?
315	The City of Seaside or the Seaside Watermaster should consider requesting membership in the Technical Committee.
316	Why was 2004 groundwater elevation used for this MO?
329	Are the MT and MO for the 180/400 Subbasin approximately -8 and -3.4 near Well MW-B-05-180? If not, why are -8 and-3.4 the MT and MO for this well?
329	1992 to 1998 data for MW-OU2-29-180 and MW-B-05-180 seem to be skewed and may need to be ignored when determining MT and MO.

Review Comments
Marina Coast Water District GSA Groundwater Sustainability Plan

Page Label	Comments
330	Is this one out-lier determining the MT of -13.3 for MP-BW-42-295. (see MT-10 for adjacent Well MW-OU2-66-180).
335	Setting the MTs to 2015 groundwater elevations seems to contradict the goal of preventing seawater intrusion.
342	Can the following statement be clarified to state whether the proposed MTs and MOs help Seaside Basin obtain its adjudication requirements: "Monterey Subbasin minimum thresholds do not prevent the Seaside basin from meeting its adjudication requirements, including the occurrence of Material Injury."
392	Should a column be added to Table 9-1 for "... a description of the measurable objective that is expected to benefit from the project or management action [354.44(a)(1)"? If not, is this information given elsewhere?
394	If the extraction barrier is a necessary component of Project R2 (see Section 9.4.2.7 which states it is a precursor), should it be included here? If not, why is the seawater extraction barrier not included as a separate project in Table 9-1?
394	Please confirm estimated cost of $172M fro R1 (Section 9.4.1.7 seems to indicate $181M)
396	The costs for pilot scale modeling should be moved from Project M4 to Project M3.
396	The demand for 1,427 AFY irrigation water at a unit production cost of $1,600/AF seems high. Section 9.4.6.7 states "MCWD's 2020 UWMP estimates that 950 AFY of landscape irrigation demand can be met by recycled water by 2030 and 1,270 AFY by 2040"
398	Should the costs shown here only reflect costs to the MCWD GSA?
398	The Seaside Watermaster supports the construction of a facility that would allow water to be imported and injected into the Seaside Basin (see letter to M1W et al dated May 24, 2021). Can this section be clarified to state potential actions that will be implemented by the GSA to support the Seaside Watermaster desire to import water?
399	Should the costs shown here only reflect costs to the MCWD GSA?
399	Projects I5 and I6 appear to be the same action. Please clarify how one could be implemented without the other.
399	Please consider adding an action that supports modeling integration with Seaside Subbasin.
400	Should Project I9 be modified to include wells that become non-productive due to such things as high TDS?
403	Section 9.4 would be more readable if the organization of project descriptions followed Table 9-1 and used the P/MA # found there.
407	Does the FORA HCP have water rights and flow prescriptions for the Salinas River?
407	Since the GSP states that potable water could be delivered to Zone 2C by direct diversion and treatment from the Salinas River during certain months with some minor permit modifications, it should also be possible to deliver irrigation water through direct diversion. Should this be explored and promoted as an alternative for providing irrigation water to supplement the more expensive treated water from Pure Water Monterey (i.e. $1,100/AF versus $1,600/AF, respectively)?
411	Where is the scope of work and capital costs described for the Seawater Intrusion Extraction Barrier Project?
411	Project R2 states "The plant will produce approximately 15,000 AFY of potable water for use." Chapter 6 states that there is approx increased demand of 5,300 AFY. Why is desal plant being proposed that could provide almost 3 times the future demand?
411	Is Project R2 substantially different than the Regional Project as proposed by Cal Am? If not, why is "Further analysis and scoping ... needed to determine the exact location of the desalination plant, end uses, and desalination technology"? If so, how are they different?
411	Table 9-1 does not include "Priority Project 6." Please clarify where this project is tabulated.
412	Please clarify how extracting an additional 35,000 AFY from the basin reduces groundwater extraction and will "either raise groundwater elevations or reduce the rate of groundwater elevation decline over time."
412	Please clarify if the extraction wells are extracting 100% seawater. If not, how is this project able to reduce groundwater extraction.
412	Please clarify how extracting water from the basin will reduce any potential for land subsidence.
412	Please clarify " This would reduce groundwater extraction by that amount, increase the Subbasin's groundwater storage." Unless the extraction wells are pumping 100% seawater, there is not a one-for-one benefit for reduction in groundwater extraction.
413	Please clarify alternatives for discharging and/or reusing extracted brackish water. If none, please clarify if there are potential cost effective alternatives to Project R2.
416	Please clarify where this cost data is derived from.
417	Why is the seawater intrusion extraction barrier project not better described in this section?
440	Please clarify how IPR would increase groundwater elevations.
440	Since Project M3 is not a supplemental water supply project, it is unclear how it would "add" water to the aquifer for future development? Please clarify.
443	Have all the capital expenditures been paid for the 600 AFY? If not, please clarify the investment needed to reimburse the capital expenditures and debt servicing for the 600 AFY.
443	Please clarify if the "soft costs" provided here include debt servicing. If not, why not?

Marina Coast Water District GSA Groundwater Sustainability Plan

Page Label	Comments
445	Please confirm that RUWAP pipe extends south of Coe Ave in GJM Blvd.
487	Can the Monterey Subbasin Model be coordinated with the Seaside Basin model to simulate conditions across the subbasins?
491	Addressing potential overdraft could be managed by producing documents such as a monitoring and management plan and a management action plan that addresses policies and procedures to monitor and respond to water elevation concerns.
497	Can extraction wells be added to the monitoring network?
497	The annual report could also address if milestones and goals are being attained and, if necessary, potential corrective actions that may be employed to respond to deviations from goals.
507	What is the estimated additional costs to rate payers if no grant funding becomes available?
508	Please clarify why Administration and Legal costs are 30% of the total cost.

Re: Public Comment Letter for Monterey Subbasin Draft GSP

Dear Donna Meyers,

On behalf of the above-listed organizations, we appreciate the opportunity to comment on the Draft Groundwater Sustainability Plan (GSP) for the Monterey Subbasin being prepared under the Sustainable Groundwater Management Act (SGMA). Our organizations are deeply engaged in and committed to the successful implementation of SGMA because we understand that groundwater is critical for the resilience of California's water portfolio, particularly in light of changing climate. Under the requirements of SGMA, Groundwater Sustainability Agencies (GSAs) must consider the interests of all beneficial uses and users of groundwater, such as domestic well owners, environmental users, surface water users, federal government, California Native American tribes and disadvantaged communities (Water Code 10723.2).

As stakeholder representatives for beneficial users of groundwater, our GSP review focuses on how well disadvantaged communities, drinking water users, tribes, climate change, and the environment were addressed in the GSP. While we appreciate that some basins have consulted us directly via focus groups, workshops, and working groups, we are providing public comment letters to all GSAs as a means to engage in the development of 2022 GSPs across the state. Recognizing that GSPs are complicated and resource intensive to develop, the intention of this letter is to provide constructive stakeholder feedback that can improve the GSP prior to submission to the State.

Based on our review, we have significant concerns regarding the treatment of key beneficial users in the Draft GSP and consider the GSP to be **insufficient** under SGMA. We highlight the following findings:

1. Beneficial uses and users **are not sufficiently** considered in GSP development.
    a. Human Right to Water considerations **are not sufficiently** incorporated.
    b. Public trust resources **are not sufficiently** considered.
    c. Impacts of Minimum Thresholds, Measurable Objectives and Undesirable Results on beneficial uses and users **are not sufficiently** analyzed.
2. Climate change **is not sufficiently** considered.
3. Data gaps **are not sufficiently** identified and the GSP **needs additional plans** to eliminate them.

4. Projects and Management Actions **do not sufficiently consider** potential impacts or benefits to beneficial uses and users.

Our specific comments related to the deficiencies of the Monterey Subbasin Draft GSP along with recommendations on how to reconcile them, are provided in detail in **Attachment A.**

Please refer to the enclosed list of attachments for additional technical recommendations:

Attachment A	GSP Specific Comments
Attachment B	SGMA Tools to address DAC, drinking water, and environmental beneficial uses and users
Attachment C	Freshwater species located in the basin
Attachment D	The Nature Conservancy's "Identifying GDEs under SGMA: Best Practices for using the NC Dataset"
Attachment E	Maps of representative monitoring sites in relation to key beneficial users

Thank you for fully considering our comments as you finalize your GSP.

Attachment A

Specific Comments on the Monterey Subbasin Draft Groundwater Sustainability Plan

1. Consideration of Beneficial Uses and Users in GSP development

Consideration of beneficial uses and users in GSP development is contingent upon adequate identification and engagement of the appropriate stakeholders. The (A) identification, (B) engagement, and (C) consideration of disadvantaged communities, drinking water users, tribes,[1] groundwater dependent ecosystems, streams, wetlands, and freshwater species are essential for ensuring the GSP integrates existing state policies on the Human Right to Water and the Public Trust Doctrine.

A. Identification of Key Beneficial Uses and Users

Disadvantaged Communities and Drinking Water Users

The identification of Disadvantaged Communities (DACs) and drinking water users is **incomplete**. The GSP provides information on DACs, including identification by name and location on a map (Figure 1), and identifying the water source for DAC members. However, the GSP fails to clearly state the population of each DAC.

The GSP provides a density map of domestic wells in the subbasin (Figure 3-7). However, the plan fails to provide depth of these wells (such as minimum well depth, average well depth, or depth range) within the subbasin.

These missing elements are required for the GSA to fully understand the specific interests and water demands of these beneficial users, and to support the consideration of beneficial users in the development of sustainable management criteria and selection of projects and management actions.

RECOMMENDATIONS
• Provide the population of each identified DAC. • Include a map showing domestic well locations and average well depth across the subbasin.

Interconnected Surface Waters

The identification of Interconnected Surface Waters (ISWs) is **insufficient**, due to lack of supporting information provided for the ISW analysis. The GSP does not present a map of interconnected stream reaches in the subbasin. Furthermore, the GSP does not show the location of groundwater wells or stream gauges in the subbasin, or provide description of temporal availability of groundwater data.

[1] Our letter provides a review of the identification and consideration of federally recognized tribes (Data source: SGMA Data viewer) within the GSP from non-tribal members and NGOs. Based on the likely incomplete information available to our organizations for this review, we recommend that the GSA utilize the California Department of Water Resources' "Engagement with Tribal Governments" Guidance Document (https://water.ca.gov/Programs/Groundwater-Management/SGMA-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents) to comprehensively address these important beneficial users in their GSP.

The GSP presents maps showing depth-to-groundwater contours for depths within 20 feet of the ground surface for two dates, fall 2017 and fall 2019. The GSP does not present an explanation of why 20 feet was chosen for the maximum depth shown on the contour maps. Furthermore, using seasonal groundwater elevation data over multiple water year types is an essential component of identifying ISWs. The use of two fall dates does not reflect the temporal (seasonal and interannual) variability inherent in California's climate.

RECOMMENDATIONS

- Describe available groundwater elevation data and stream flow data in the subbasin. ISWs are best analyzed using depth-to-groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought), to determine the range of depth and capture the variability in environmental conditions inherent in California's climate.

- Provide a map of stream reaches in the subbasin. Overlay the stream reaches with full depth-to-groundwater contour maps (not just to 20 feet below ground surface) to illustrate groundwater depths and the groundwater gradient near the stream reaches. Show the location of groundwater wells in the subbasin used to create the contour maps.

- For the depth-to-groundwater contour maps, use the best practices presented in Attachment D. Specifically, ensure that the first step is contouring groundwater elevations, and then subtracting this layer from land surface elevations from a Digital Elevation Model (DEM) to estimate depth-to-groundwater contours across the landscape. This will provide accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found.

- On the map of stream reaches, consider any segments with data gaps as potential ISWs and clearly mark them as such. Describe data gaps for the ISW analysis. Reconcile these data gaps with specific measures (shallow monitoring wells, stream gauges, and nested/clustered wells) along surface water features in the Monitoring Network section of the GSP.

Groundwater Dependent Ecosystems

The identification of Groundwater Dependent Ecosystems (GDEs) is **insufficient**, due to a lack of supporting information provided for the GDE analysis. The GSP took initial steps to identify and map GDEs using the Natural Communities Commonly Associated with Groundwater dataset (NC dataset). Additional local habitat management plans and studies were used to map GDEs located at the City of Marina coastal vernal ponds and Fort Ord wetlands. The GSP presents GDEs on Figure 5-37 and has retained all GDEs from these sources as potential GDEs in the GSP.

The GSP states (p. 5-68): *"These potential GDEs within the former Fort Ord are located within the federal land areas of the Subbasin not subject to SGMA."* However, SGMA states plans shall include "efforts to develop relationships with State and Federal regulatory agencies" [Water Code §10727.4(j)], and that "The federal government...may voluntarily agree to participate in the preparation and administration of a groundwater sustainability plan" [Water Code §10720.3(c)]. Finally, SGMA defines the federal government as a beneficial user of groundwater [Water Code §10723.2(g)]. Please include information on what steps were taken to address these requirements.

The GSP does not attempt to verify the NC dataset with groundwater data, however. While the GSP does acknowledge that shallow groundwater data in areas near GDEs is a data gap, no map is provided that shows the location of existing groundwater wells in the subbasin, or a description of spatial and temporal availability of existing groundwater data. Describing groundwater conditions within the basin's GDEs is an essential precursor to identifying data/monitoring gaps and evaluating potential effects on GDEs when establishing SMCs.

While the GSP discusses the vegetation communities at the City of Marina coastal vernal ponds observed during a site visit in June 2020, this is the only mention of vegetation communities within the subbasin's GDEs. The GSP does not provide further discussion or an inventory of the flora or fauna species present in the subbasin's GDEs or acknowledge endangered, threatened, or special status species in the subbasin.

RECOMMENDATIONS
• Discuss available shallow groundwater data. Use depth-to-groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. We recommend that a baseline period (10 years from 2005 to 2015) be established to characterize groundwater conditions over multiple water year types. Refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. • Provide depth-to-groundwater contour maps, noting the best practices presented in Attachment D. Specifically, ensure that the first step is contouring groundwater elevations, and then subtracting this layer from land surface elevations from a digital elevation model (DEM) to estimate depth-to-groundwater contours across the landscape. • Provide a complete inventory, map, or description of fauna (e.g., birds, fish, amphibian) and flora (e.g., plants) species in the subbasin (see Attachment C of this letter for a list of freshwater species located in the Monterey Subbasin). Note any threatened or endangered species. • Provide further information about the steps taken to involve or collaborate with the federal government regarding potential GDEs located within the former Fort Ord area.

Native Vegetation and Managed Wetlands

Native vegetation and managed wetlands are water use sectors that are required to be included in the water budget.[2,3] The integration of native vegetation into the water budget is **insufficient**. The GSP text discusses evapotranspiration, but combines crop, urban, and native evapotranspiration in the discussion. Despite explicit mention that evapotranspiration is included in the Soil Moisture Budget (SMB) model, no evapotranspiration results for the land surface

[2] "'Water use sector' refers to categories of water demand based on the general land uses to which the water is applied, including urban, industrial, agricultural, managed wetlands, managed recharge, and native vegetation." [23 CCR §351(al)]

[3] "The water budget shall quantify the following, either through direct measurements or estimates based on data: (3) Outflows from the groundwater system by water use sector, including evapotranspiration, groundwater extraction, groundwater discharge to surface water sources, and subsurface groundwater outflow." [23 CCR §354.18]

system are included in the GSP. The omission of explicit water demands for native vegetation is problematic because key environmental uses of groundwater are not being accounted for as water supply decisions are made using this budget, nor will they likely be considered in project and management actions. Managed wetlands are not mentioned in the GSP and are not included in the water budgets.

RECOMMENDATION
● Quantify and present all water use sector demands in the historical, current, and projected water budgets with individual line items for each water use sector, including native vegetation and managed wetlands (if present).

B. Engaging Stakeholders

Stakeholder Engagement During GSP Development
Stakeholder engagement during GSP development is **sufficient**. SGMA's requirement for public notice and engagement of stakeholders is fully met by the description in the Communications and Stakeholder Engagement section (Chapter 2).[4]

The GSA's outreach activities include an Advisory Committee including representation by underrepresented communities (URCs), rural residential well owners, and environmental stakeholders, Marina Coast Water District (MCWD) GSA Board Meetings, stakeholder workshops, and one-on-one meetings with interested parties.

Despite the outreach to DACs, there is no specific pathway for feedback from DAC residents and representatives to be considered and included in the GSP and its implementation.

We note specific engagement with DACs and environmental organizations during the GSP implementation process. The GSP states (p. 10-11): *"MCWD and SVBGSA's Stakeholder Communication and Engagement Plans (SCEPs) will continue to be refined, updated, and executed during GSP implementation."* These activities include subbasin planning committees transitioning to implementation committees , engaging residents of DACs during GSP implementation through engagement of MCWD customers and coordination with the City of Marina, and GSAs routine reporting to the public about GSP implementation and progress towards sustainability and needs for efficient groundwater use.

RECOMMENDATIONS

[4] "A communication section of the Plan shall include a requirement that the GSP identify how it encourages the active involvement of diverse social, cultural, and economic elements of the population within the basin." [23 CCR §354.10(d)(3)]

- In the Communications and Stakeholder Engagement section, provide more information on how DACs and environmental stakeholders were included in the Advisory Committee and the role that it plays in GSP development.

- DAC and environmental stakeholder engagement should be improved by incorporating feedback and recommendations from DAC and environmental stakeholders engaged in the GSP process.

- Further describe efforts to engage with stakeholders during the GSP *implementation* phase in the Communications and Stakeholder Engagement section of the GSP. Refer to Attachment B for specific recommendations on how to actively engage stakeholders during all phases of the GSP process.

- Utilize DWR's tribal engagement guidance to comprehensively address all tribes and tribal interests in the subbasin within the GSP.[5]

C. Considering Beneficial Uses and Users When Establishing Sustainable Management Criteria and Analyzing Impacts on Beneficial Uses and Users

The consideration of beneficial uses and users when establishing sustainable management criteria (SMC) is **insufficient**. The consideration of potential impacts on all beneficial users of groundwater in the basin are required when defining undesirable results and establishing minimum thresholds.[6,7,8]

Disadvantaged Communities and Drinking Water Users

For chronic lowering of groundwater levels, the GSP discusses minimum thresholds impact on domestic wells (Section 8.7.3.2). The GSP states (p. 8-35): *"In the Corral de Tierra Area, 100% of the domestic wells should have at least 25 feet of water in them to remain operable if groundwater elevations are at minimum thresholds. Therefore, the minimum thresholds appear to be reasonably protective for domestic users.*" However, the analysis was only based on 19 wells out of the total 169 domestic wells in the OSWCR database. Furthermore, the GSP states (p. 8-35): *"Some domestic wells may draw water from shallow, perched groundwater that is not managed in this GSP.*" The GSP states (p. 4-36): *"There is one single principal aquifer in the Corral de Tierra Area called the El Toro Primary Aquifer System."* The shallow perched zones are part of the primary aquifer system and are still governed by the requirements of SGMA. The current analysis, which only considers 19 out of 169 wells, is insufficient and does not use best available information, for example including Public Land Survey System (PLSS) section location data, as was used in the 180/400 Foot Aquifer GSP.

---

[5] Engagement with Tribal Governments Guidance Document. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Sustainable-Groundwater-Management/Best-Management-Practices-and-Guidance-Documents/Files/Guidance-Doc-for-SGM-Engagement-with-Tribal-Govt_ay_19.pdf

[6] "The description of undesirable results shall include [...] potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results." [23 CCR §354.26(b)(3)]

[7] "The description of minimum thresholds shall include [...] how minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests." [23 CCR §354.28(b)(4)]

[8] "The description of minimum thresholds shall include [...] how state, federal, or local standards relate to the relevant sustainability indicator. If the minimum threshold differs from other regulatory standards, the agency shall explain the nature of and the basis for the difference." [23 CCR §354.28(b)(5)]

The GSP states (p. 8-20): *"Groundwater elevation minimum thresholds in the Corral de Tierra Area are defined as follows: Groundwater elevation observed in 2015 in the El Toro Primary Aquifer System."* The GSP does not describe or analyze the impact on DACs and domestic well owners to minimum thresholds that are set to drought-level groundwater elevations, nor does it describe how the existing groundwater level minimum thresholds will avoid significant and unreasonable impacts on DACs and domestic well users beyond 2015 and be consistent with Human Right to Water policy.[9]

For degraded water quality, the GSP identifies constituents of concern (COCs) within the subbasin in Table 8-5, which provides a list of constituents and number of wells that must exceed regulatory standards in order to trigger minimum thresholds. However, the GSP fails to provide justification for how those numbers were selected. The GSP also sets measurable objectives identical to minimum thresholds. The exceedance of minimum thresholds is supposed to trigger additional actions but since minimum thresholds in this plan are identified as measurable objectives, it is unclear what action is triggered. Furthermore, the regulatory standards are not explicitly provided in the GSP.

RECOMMENDATIONS

Chronic Lowering of Groundwater Levels

- Describe direct and indirect impacts on DACs and drinking water users when defining undesirable results for chronic lowering of groundwater levels. For the analysis of minimum threshold impact on domestic wells, use best available information such as Public Land Survey System (PLSS) section location data.

- Establish minimum thresholds at the representative monitoring wells that account for the specific undesirable results the GSA has determined for the subbasin.

Degraded Water Quality

- Describe direct and indirect impacts on DACs and drinking water users when defining undesirable results for degraded water quality. For specific guidance on how to consider these users, refer to "Guide to Protecting Water Quality Under the Sustainable Groundwater Management Act."[10]

- Set measurable objectives at lower levels than minimum thresholds (i.e., indicative of better water quality).

- Set concentration-based minimum thresholds and measurable objectives for COCs in the subbasin that are impacted by groundwater use and/or management. Ensure they align with drinking water standards.[11]

[9] California Water Code §106.3. Available at: https://leginfo.legislature.ca.gov/faces/codes_displaySection.xhtml?lawCode=WAT&sectionNum=106.3
[10] Guide to Protecting Water Quality under the Sustainable Groundwater Management Act https://d3n8a8pro7vhmx.cloudfront.net/communitywatercenter/pages/293/attachments/original/1559328858/Guide_to_Protecting_Drinking_Water_Quality_Under_the_Sustainable_Groundwater_Management_Act.pdf?1559328858.
[11] "Degraded Water Quality [...] collect sufficient spatial and temporal data from each applicable principal aquifer to determine groundwater quality trends for water quality indicators, as determined by the Agency, to address known water quality issues." [23 CCR §354.34(c)(4)]

- Evaluate the cumulative or indirect impacts of proposed minimum thresholds for degraded water quality on DACs and drinking water users.

Groundwater Dependent Ecosystems and Interconnected Surface Waters

Sustainable management criteria for chronic lowering of groundwater levels provided in the GSP do not consider potential impacts to environmental beneficial users. The GSP neither describes nor analyzes direct or indirect impacts on environmental users of groundwater when defining undesirable results. This is problematic because without identifying potential impacts to GDEs, minimum thresholds may compromise, or even destroy, these environmental beneficial users. Since GDEs are present in the subbasin, they must be considered when developing SMC.

Sustainable management criteria for depletion of interconnected surface water are established by proxy using minimum shallow groundwater elevations historically observed between 1995 and 2015 near locations of interconnected surface water. To describe impacts to ecological surface water users, the GSP states (p. 8-76): *"There are no known flow prescriptions on the El Toro Creek or any tributaries in the Corral de Tierra Area. Therefore, the current level of depletion has not violated any ecological flow requirements. This conclusion is not meant to imply that depletions do not impact potential species living in or near surface water bodies in the Corral de Tierra Area. However, any impacts that may be occurring have not risen to a level that triggers regulatory intervention. Therefore, the impacts from current rates of depletion on ecological surface water users adjacent to the El Toro Creek are not unreasonable."* The GSP makes no attempt to evaluate the impacts of the proposed minimum threshold on environmental beneficial users of surface water. The GSP does not explain how the chosen minimum thresholds and measurable objectives avoid significant and unreasonable effects on surface water beneficial users in the subbasin, such as increased mortality and inability to perform key life processes (e.g., reproduction, migration).

RECOMMENDATIONS

- When defining undesirable results for chronic lowering of groundwater levels, provide specifics on what biological responses (e.g., extent of habitat, growth, recruitment rates) would best characterize a significant and unreasonable impact to GDEs. Undesirable results to environmental users occur when 'significant and unreasonable' effects on beneficial users are caused by one of the sustainability indicators (i.e., chronic lowering of groundwater levels, degraded water quality, or depletion of interconnected surface water). Thus, potential impacts on environmental beneficial uses and users need to be considered when defining undesirable results in the subbasin.[12] Defining undesirable results is the crucial first step before the minimum thresholds can be determined.[13]

- When defining undesirable results for depletion of interconnected surface water, include a description of potential impacts on instream habitats within ISWs when

[12] "The description of undesirable results shall include [...] potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results". [23 CCR §354.26(b)(3)]

[13] The description of minimum thresholds shall include [...] how minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests." [23 CCR §354.28(b)(4)]

minimum thresholds in the subbasin are reached.[14] The GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of interconnected surface waters as these environmental users could be left unprotected by the GSP. These recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law.[6,15]

- When establishing SMC for the subbasin, consider that the SGMA statute [Water Code §10727.4(l)] specifically calls out that GSPs shall include "impacts on groundwater dependent ecosystems".

2. Climate Change

The SGMA statute identifies climate change as a significant threat to groundwater resources and one that must be examined and incorporated in the GSPs. The GSP Regulations require integration of climate change into the projected water budget to ensure that projects and management actions sufficiently account for the range of potential climate futures.[16] The effects of climate change can intensify the impacts of water stress on GDEs, making available shallow groundwater resources more critical for their survival. Research shows that GDEs are more likely to succumb to water stress and rely more on groundwater during times of drought.[17] When shallow groundwater is unavailable, riparian forests can die off and key life processes (e.g., migration and spawning) for aquatic organisms, such as steelhead, can be impeded.

The integration of climate change into the projected water budget is **insufficient**. The GSP incorporates climate change into the projected water budget using DWR change factors for 2030 and 2070. However, the plan does not consider multiple climate scenarios (e.g., the 2070 extremely wet and extremely dry climate scenarios) in the projected water budget. The GSP should clearly and transparently incorporate the extremely wet and dry scenarios provided by DWR into projected water budgets or select more appropriate extreme scenarios for the subbasin. While these extreme scenarios may have a lower likelihood of occurring, their consequences could be significant and their inclusion can help identify important vulnerabilities in the subbasin's approach to groundwater management.

If the water budgets are incomplete, including the omission of extremely wet and dry scenarios, then there is increased uncertainty in virtually every subsequent calculation used to plan for projects, derive measurable objectives, and set minimum thresholds. Plans that do not adequately include climate change projections may underestimate future impacts on vulnerable beneficial users of groundwater such as ecosystems and domestic well owners.

---

[14] "The minimum threshold for depletions of interconnected surface water shall be the rate or volume of surface water depletions caused by groundwater use that has adverse impacts on beneficial uses of the surface water and may lead to undesirable results." [23 CCR §354.28(c)(6)]

[15] Rohde MM, Seapy B, Rogers R, Castañeda X, editors. 2019. Critical Species LookBook: A compendium of California's threatened and endangered species for sustainable groundwater management. The Nature Conservancy, San Francisco, California. Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/Critical_Species_LookBook_91819.pdf

[16] "Each Plan shall rely on the best available information and best available science to quantify the water budget for the basin in order to provide an understanding of historical and projected hydrology, water demand, water supply, land use, population, climate change, sea level rise, groundwater and surface water interaction, and subsurface groundwater flow." [23 CCR §354.18(e)]

[17] Condon et al. 2020. Evapotranspiration depletes groundwater under warming over the contiguous United States. Nature Communications. Available at: https://www.nature.com/articles/s41467-020-14688-0

The GSP states that climate change is incorporated into key inputs (e.g., precipitation, evapotranspiration, surface water flow, and sea level rise) of the projected water budget. However, we were unable to confirm this since Appendix 6B (Monterey Subbasin Groundwater Flow Model Documentation) was not available at the time of the Draft GSP's publication.

RECOMMENDATIONS

- Integrate climate change, including extremely wet and dry scenarios, into all elements of the projected water budget to form the basis for development of sustainable management criteria and projects and management actions.
- Provide details in the GSP on how climate change was incorporated into key inputs (e.g., precipitation, evapotranspiration, surface water flow, and sea level rise) of the water budget.
- Incorporate climate change scenarios into projects and management actions.

3. Data Gaps

The consideration of beneficial users when establishing monitoring networks is **insufficient**, due to lack of specific plans to increase the Representative Monitoring Sites (RMSs) in the monitoring network that represent water quality conditions around DACs and domestic wells and shallow groundwater elevations around GDEs and ISWs in the subbasin. These beneficial users may remain unprotected by the GSP without adequate monitoring and identification of data gaps in the shallow aquifer. The Plan therefore fails to meet SGMA's requirements for the monitoring network.[18]

Figure 7-1 through Figure 7-6 show the locations of the groundwater elevation monitoring network and wells selected for the RMS network within the Marina-Ord Area and the Corral De Tiera Area. Refer to Attachment E for maps of these monitoring sites, plotted by depth, in relation to key beneficial users of groundwater. The monitoring network that represents shallow groundwater elevations around DACs and domestic wells in the subbasin appears sufficient in terms of spatial and depth distribution.

Figure 7-17 (Locations of Wells in the Groundwater Quality Monitoring Network) shows that no water quality monitoring wells are located across portions of the subbasin near DACs and domestic wells. The monitoring network that represents water quality conditions around DACs and domestic wells in the subbasin is insufficient in terms of spatial and depth distribution. Note we were unable to create a map of water quality RMSs since Appendix 7F was not available at the time of the Draft GSP's publication.

The GSP discusses plans to install a new shallow monitoring well in the Corral de Tierra Area to assess ISWs. The GSP does not, however, discuss plans to fill data gaps for GDEs, despite acknowledging significant GDE data gaps in the GDE section of the GSP.

RECOMMENDATIONS

[18] "The monitoring network objectives shall be implemented to accomplish the following: [...] (2) Monitor impacts to the beneficial uses or users of groundwater." [23 CCR §354.34(b)(2)]

- Provide maps that overlay current and proposed monitoring well locations with the locations of DACs, domestic wells, GDEs, and ISWs to clearly identify potentially impacted areas.

- Increase the number of RMSs in the shallow aquifer across the subbasin as needed to adequately monitor all groundwater condition indicators across the subbasin and at appropriate depths for *all* beneficial users. Prioritize proximity to DACs, domestic wells, and GDEs when identifying new RMSs.

- Ensure groundwater elevation and water quality RMSs are monitoring groundwater conditions spatially and at the correct depth for *all* beneficial users - especially DACs, domestic wells, and GDEs.

- Describe biological monitoring that can be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

4. Addressing Beneficial Users in Projects and Management Actions

The consideration of beneficial users when developing projects and management actions is **insufficient** due to the failure to completely identify benefits or impacts of identified projects and management actions, including water quality impacts, to key beneficial users of groundwater such as GDEs, aquatic habitats, surface water users, DACs, and drinking water users. Therefore, potential project and management actions may not protect these beneficial users. Groundwater sustainability under SGMA is defined not just by sustainable yield, but by the avoidance of undesirable results for *all* beneficial users.

Section 9.4.3 documents the Multi-benefit Stream Channel Improvements and discusses its benefits including groundwater recharge. However, the project is described as a potential project that will be implemented on an as-needed basis and the GSP does not explicitly define a planning horizon within the SGMA process.

In Section 9.5.9 (Dry Well Notification System), the GSP states (p. 9-104): "*The GSA could develop or support the development of a program to assist well owners (domestic or state small and local small water systems) whose wells go dry due to declining groundwater elevations.*" The GSP states that the program could involve a notification system, monitoring triggered by lowered groundwater elevations, public outreach, "*...referral to assistance with short-term supply solutions, technical assistance to assess why it went dry, and/or long-term supply solutions*." However, no further specifics on a drinking water well impact mitigation program are provided.

RECOMMENDATIONS

- For DACs and domestic well owners, provide specific plans for implementation of a drinking water well impact mitigation program to proactively monitor and protect drinking water wells through GSP implementation. Refer to Attachment B for specific recommendations on how to implement a drinking water well mitigation program.

- For DACs and domestic well owners, include a discussion of whether potential impacts to water quality from projects and management actions could occur and how the GSAs plans to mitigate such impacts.

- Clarify the planning horizon of the described multi-benefit stream channel improvements to ensure that the project will proactively provide groundwater recharge, remove invasive species, and reduce streamflow impediments through GSP implementation.

- Recharge ponds, reservoirs, and facilities for managed stormwater recharge can be designed as multiple-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. For guidance on how to integrate multi-benefit recharge projects into your GSP, refer to the "Multi-Benefit Recharge Project Methodology Guidance Document".[19]

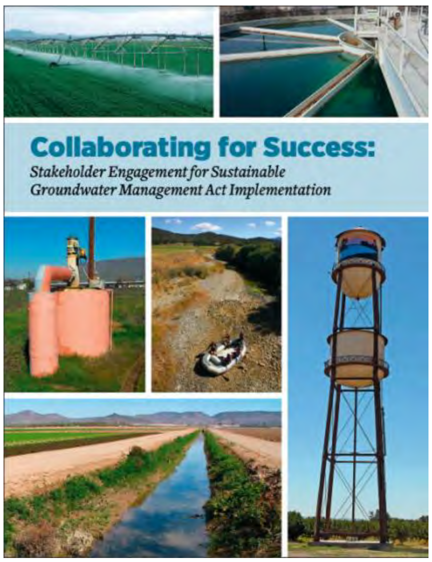
- Develop management actions that incorporate climate and water delivery uncertainties to address future water demand and prevent future undesirable results.

[19] The Nature Conservancy. 2021. Multi-Benefit Recharge Project Methodology for Inclusion in Groundwater Sustainability Plans. Sacramento. Available at: https://groundwaterresourcehub.org/sgma-tools/multi-benefit-recharge-project-methodology-guidance/

Attachment B

SGMA Tools to address DAC, drinking water, and environmental beneficial uses and users

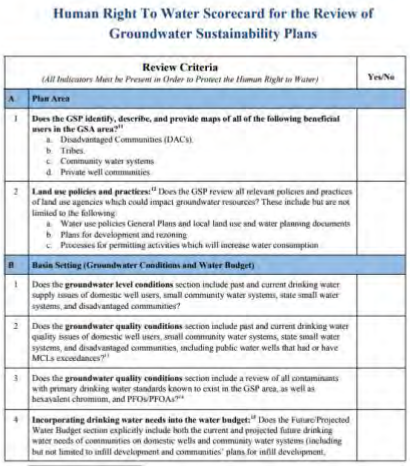
Stakeholder Engagement and Outreach



Clean Water Action, Community Water Center and Union of Concerned Scientists developed a guidance document called Collaborating for success: Stakeholder engagement for Sustainable Groundwater Management Act Implementation. It provides details on how to conduct targeted and broad outreach and engagement during Groundwater Sustainability Plan (GSP) development and implementation. Conducting a targeted outreach involves:

- Developing a robust Stakeholder Communication and Engagement plan that includes outreach at frequented locations (schools, farmers markets, religious settings, events) across the plan area to increase the involvement and participation of disadvantaged communities, drinking water users and the environmental stakeholders.
- Providing translation services during meetings and technical assistance to enable easy participation for non-English speaking stakeholders.
- GSP should adequately describe the process for requesting input from beneficial users and provide details on how input is incorporated into the GSP.

The Human Right to Water

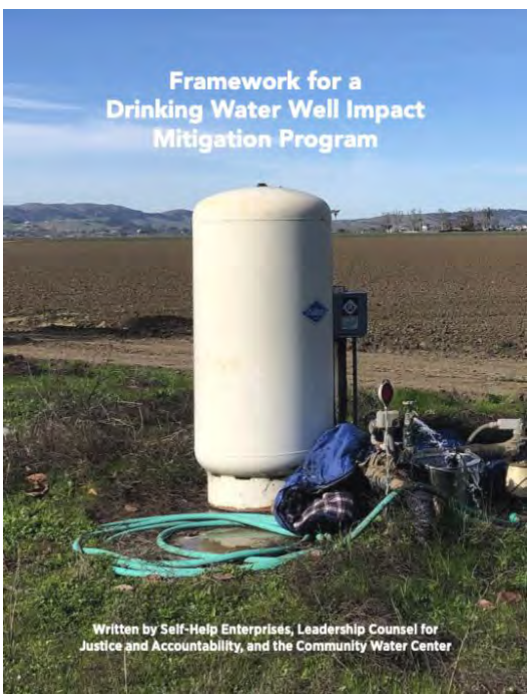


Human Right To Water Scorecard for the Review of Groundwater Sustainability Plans

	Review Criteria *(All Indicators Must be Present in Order to Protect the Human Right to Water)*	Yes/No
A	**Plan Area**	
1	**Does the GSP identify, describe, and provide maps of all of the following beneficial users in the GSA area?**[11] a. Disadvantaged Communities (DACs). b. Tribes. c. Community water systems d. Private well communities	
2	**Land use policies and practices:**[12] Does the GSP review all relevant policies and practices of land use agencies which could impact groundwater resources? These include but are not limited to the following: a. Water use policies General Plans and local land use and water planning documents b. Plans for development and rezoning c. Processes for permitting activities which will increase water consumption	
B	**Basin Setting (Groundwater Conditions and Water Budget)**	
1	Does the **groundwater level conditions** section include past and current drinking water supply issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities?	
2	Does the **groundwater quality conditions** section include past and current drinking water quality issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities, including public water wells that had or have MCLs exceedances?[13]	
3	Does the **groundwater quality conditions** section include a review of all contaminants with primary drinking water standards known to exist in the GSP area, as well as hexavalent chromium, and PFOs/PFOAs?[14]	
4	**Incorporating drinking water needs into the water budget:**[15] Does the Future/Projected Water Budget section explicitly include both the current and projected future drinking water needs of communities on domestic wells and community water systems (including but not limited to infill development and communities' plans for infill development,	

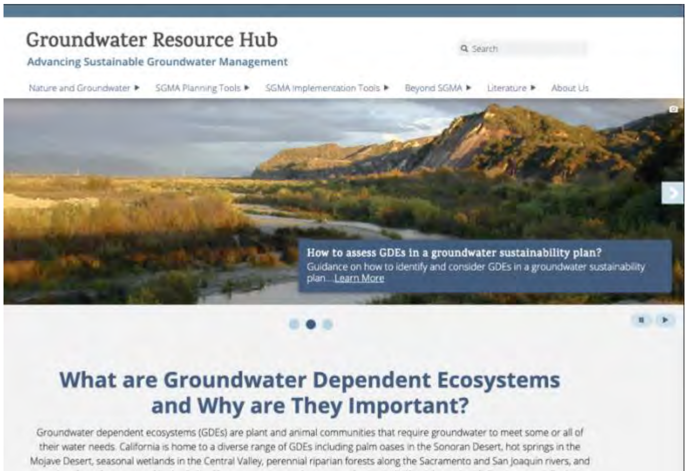
The Human Right to Water Scorecard was developed by Community Water Center, Leadership Counsel for Justice and Accountability and Self Help Enterprises to aid Groundwater Sustainability Agencies (GSAs) in prioritizing drinking water needs in SGMA. The scorecard identifies elements that must exist in GSPs to adequately protect the Human Right to Drinking water.

Drinking Water Well Impact Mitigation Framework



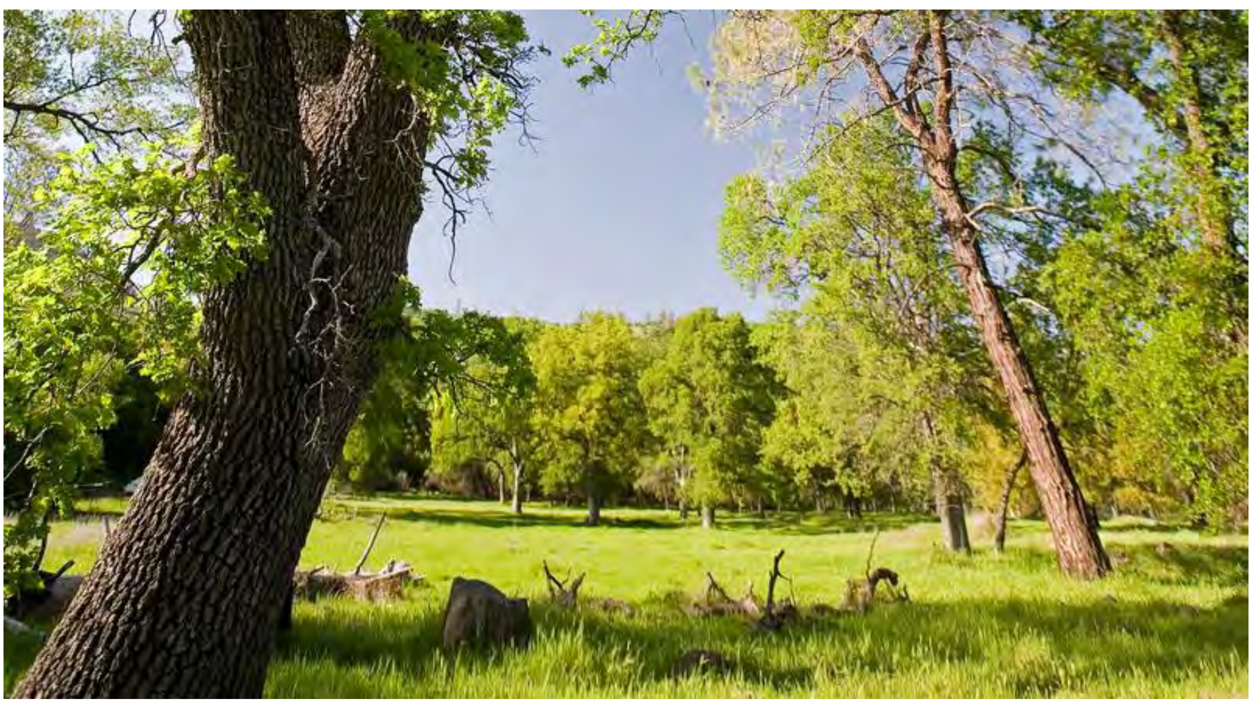
The Drinking Water Well Impact Mitigation Framework was developed by Community Water Center, Leadership Counsel for Justice and Accountability and Self Help Enterprises to aid GSAs in the development and implementation of their GSPs. The framework provides a clear roadmap for how a GSA can best structure its data gathering, monitoring network and management actions to proactively monitor and protect drinking water wells and mitigate impacts should they occur.

Groundwater Resource Hub



The Nature Conservancy has developed a suite of tools based on best available science to help GSAs, consultants, and stakeholders efficiently incorporate nature into GSPs. These tools and resources are available online at GroundwaterResourceHub.org. The Nature Conservancy's tools and resources are intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Rooting Depth Database



The Plant Rooting Depth Database provides information that can help assess whether groundwater-dependent vegetation are accessing groundwater. Actual rooting depths will depend on the plant species and site-specific conditions, such as soil type and availability of other water sources. Site-specific knowledge of depth to groundwater combined with rooting depths will help provide an understanding of the potential groundwater levels are needed to sustain GDEs.

How to use the database

The maximum rooting depth information in the Plant Rooting Depth Database is useful when verifying whether vegetation in the Natural Communities Commonly Associated with Groundwater (NC Dataset) are connected to groundwater. A 30 ft depth-to-groundwater threshold, which is based on averaged global rooting depth data for phreatophytes[1], is relevant for most plants identified in the NC Dataset since most plants have a max rooting depth of less than 30 feet. However, it is important to note that deeper thresholds are necessary for other plants that have reported maximum root depths that exceed the averaged 30 feet threshold, such as valley oak (*Quercus lobata*), Euphrates poplar (*Populus euphratica*), salt cedar (*Tamarix spp.*), and shadescale (*Atriplex confertifolia*). The Nature Conservancy advises that the reported max rooting depth for these deeper-rooted plants be used. For example, a depth-to groundwater threshold of 80 feet should be used instead of the 30 ft threshold, when verifying whether valley oak polygons from the NC Dataset are connected to groundwater. It is important to re-emphasize that actual rooting depth data are limited and will depend on the plant species and site-specific conditions such as soil and aquifer types, and availability to other water sources.

The Plant Rooting Depth Database is an Excel workbook composed of four worksheets:

1. California phreatophyte rooting depth data (included in the NC Dataset)
2. Global phreatophyte rooting depth data
3. Metadata
4. References

How the database was compiled

The Plant Rooting Depth Database is a compilation of rooting depth information for the groundwater-dependent plant species identified in the NC Dataset. Rooting depth data were compiled from published scientific literature and expert opinion through a crowdsourcing campaign. As more information becomes available, the database of rooting depths will be updated. Please Contact Us if you have additional rooting depth data for California phreatophytes.

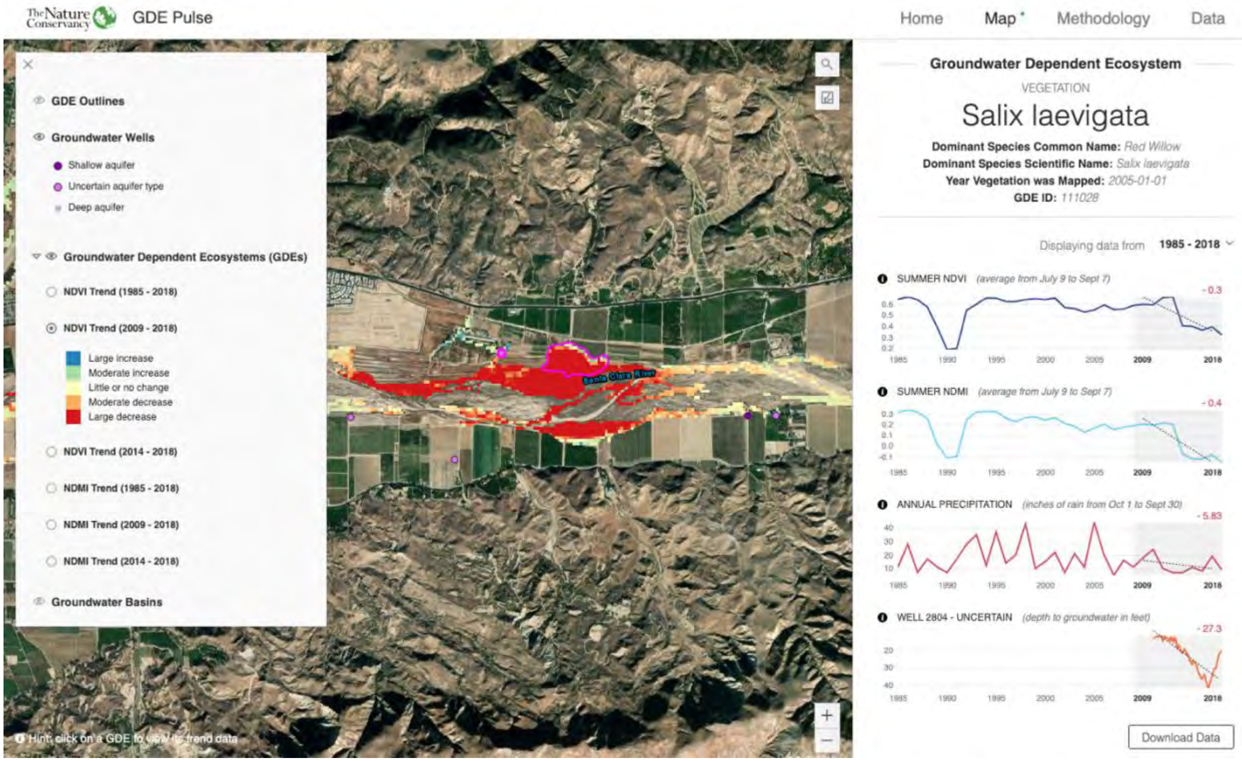
GDE Pulse



GDE Pulse is a free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data. Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset. The following datasets are available for downloading:

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

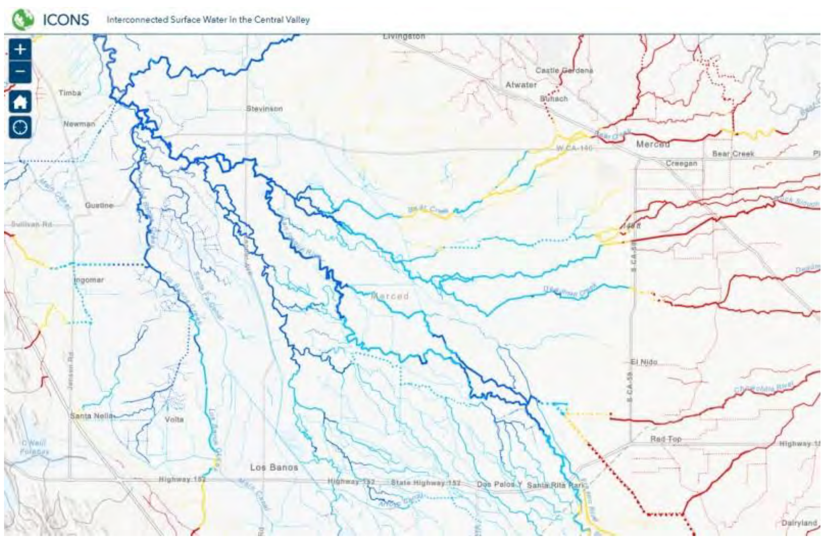
Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

ICONOS Mapper

Interconnected Surface Water in the Central Valley



ICONS maps the likely presence of interconnected surface water (ISW) in the Central Valley using depth to groundwater data. Using data from 2011-2018, the ISW dataset represents the likely connection between surface water and groundwater for rivers and streams in California's Central Valley. It includes information on the mean, maximum, and minimum depth to groundwater for each stream segment over the years with available data, as well as the likely presence of ISW based on the minimum depth to groundwater. The Nature Conservancy developed this database, with guidance and input from expert academics, consultants, and state agencies.

We developed this dataset using groundwater elevation data available online from the California Department of Water Resources (DWR). DWR only provides this data for the Central Valley. For GSAs outside of the valley, who have groundwater well measurements, we recommend following our methods to determine likely ISW in your region. The Nature Conservancy's ISW dataset should be used as a first step in reviewing ISW and should be supplemented with local or more recent groundwater depth data.

Attachment C

Freshwater Species Located in the Monterey Basin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result "depletion of interconnected surface waters", Attachment C provides a list of freshwater species located in the Monterey Basin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the basin boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015[1]. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife's BIOS[2] as well as on The Nature Conservancy's science website[3].

IDENTIFYING GDEs UNDER SGMA
Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online[1] to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)[2]. This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.

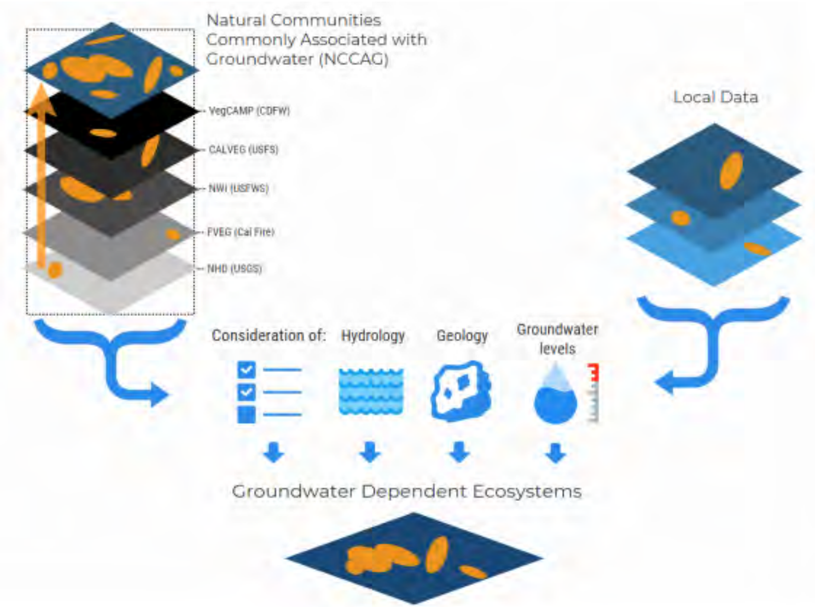

Figure 1. Considerations for GDE identification.
Source: DWR[2]

---

[1] NC Dataset Online Viewer: https://gis.water.ca.gov/app/NCDatasetViewer/

[2] California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California[3]. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset[4] on the Groundwater Resource Hub[5], a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer*.

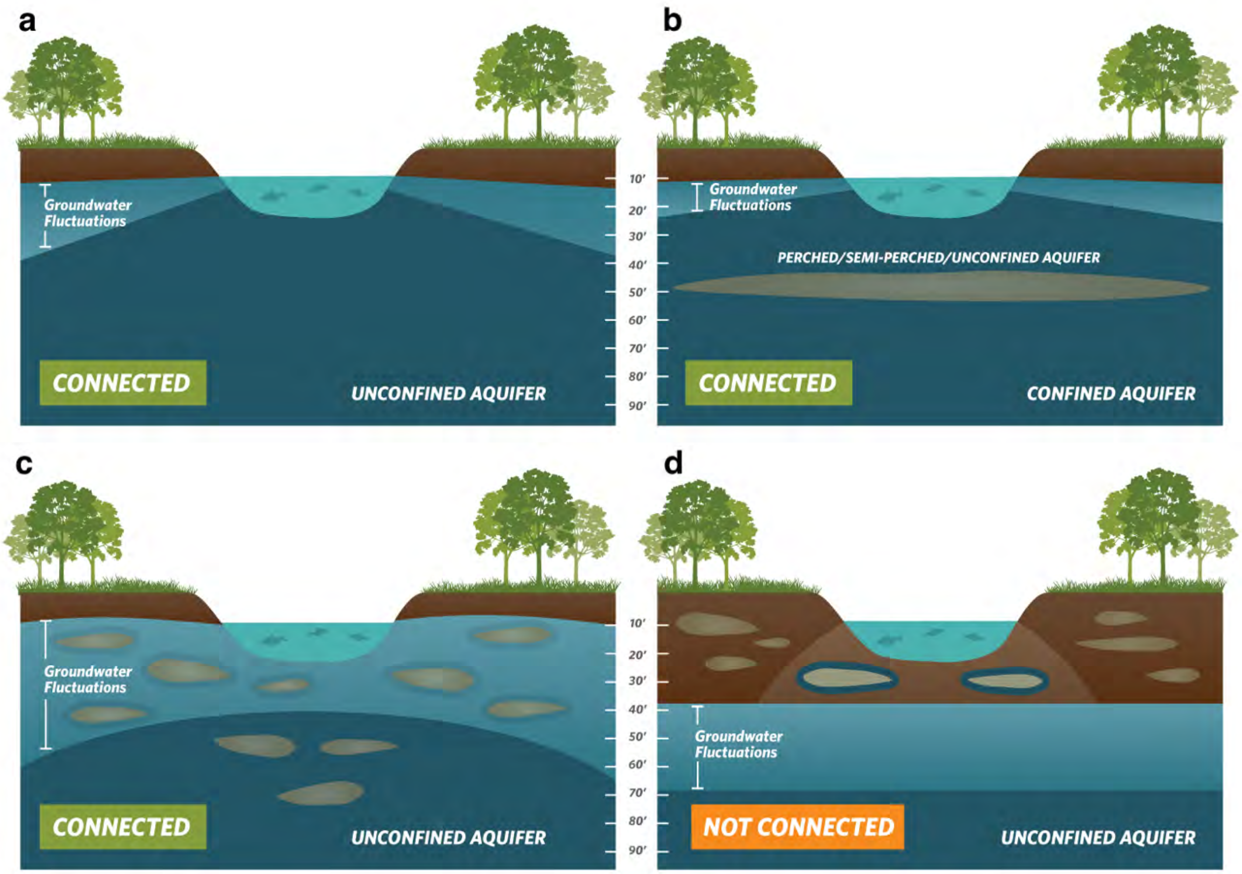

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. (b) Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. Bottom: (c) Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem's connection to groundwater. (d) Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California's climate. DWR's Best Management Practices document on water budgets[6] recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline[7] could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach[8] for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC's GDE guidance document[4], one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California's Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California's GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet[4] of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer[9]. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

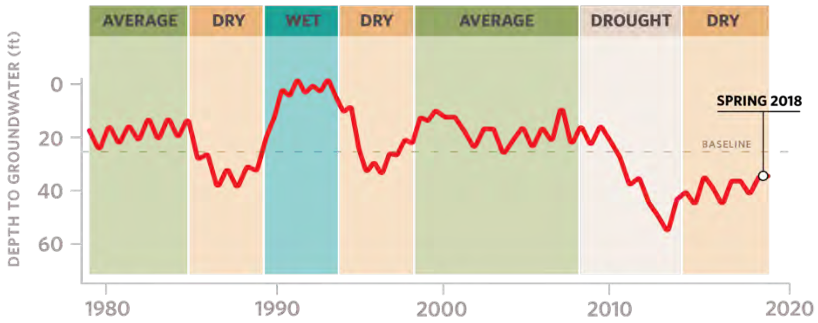

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

[7] Baseline is defined under the GSP regulations as "historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin." [23 CCR §351(e)]

[8] Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs[4]).

[9] SGMA Data Viewer: https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals[10], which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

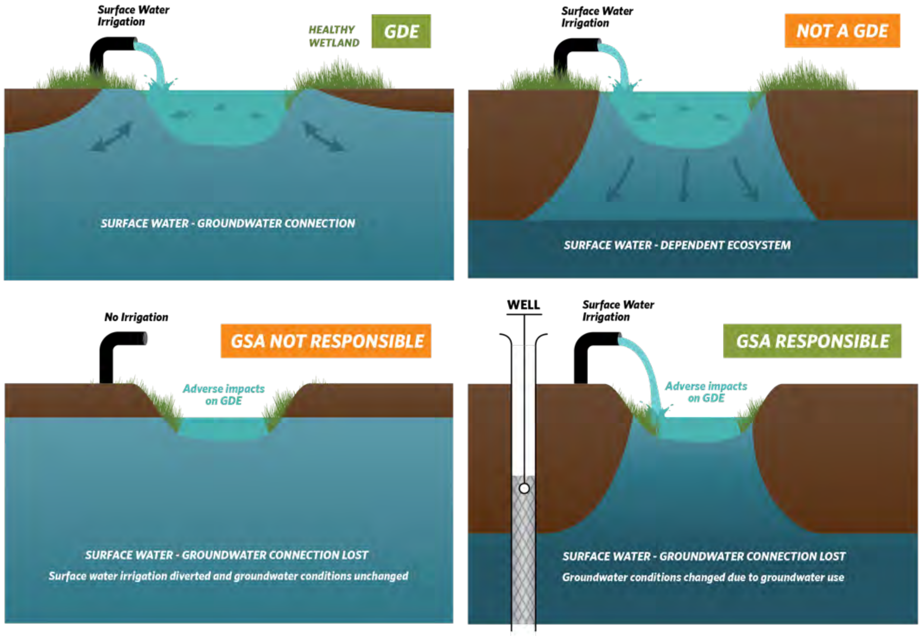

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. (Right) Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. Bottom: (Left) An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. (Right) Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

[10] For a list of environmental beneficial users of surface water by basin, visit: https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.

- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.

- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

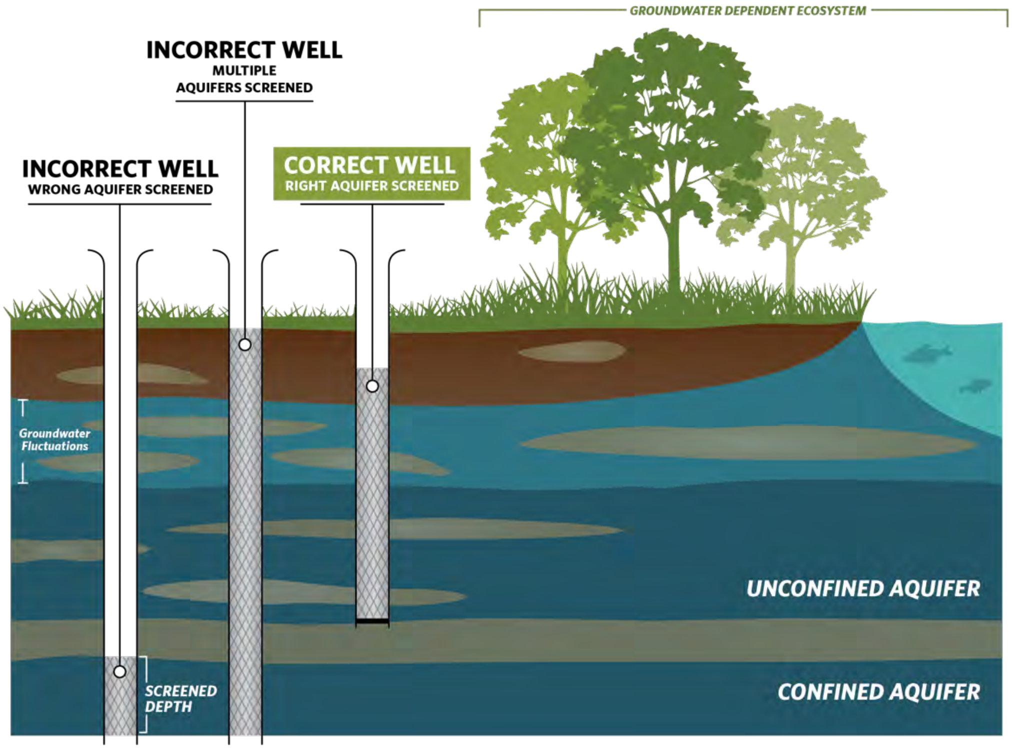

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate groundwater elevations at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)[11] to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

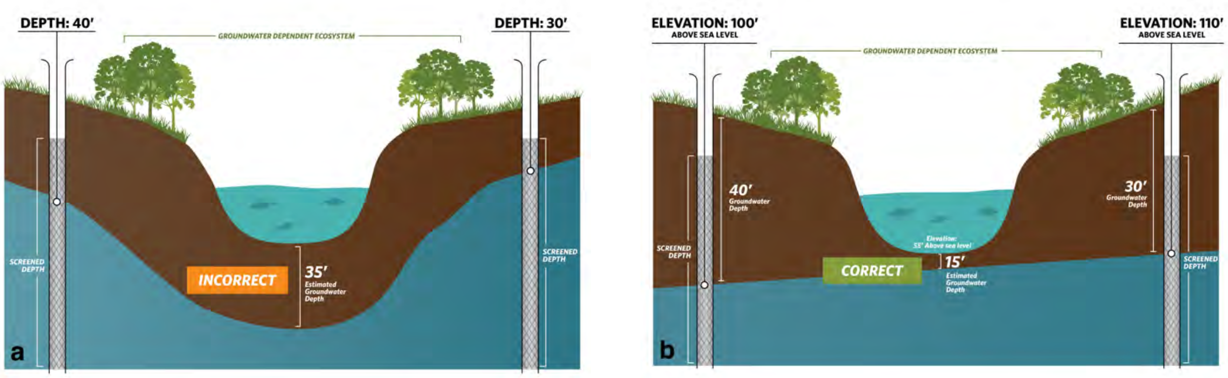

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. (b) Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

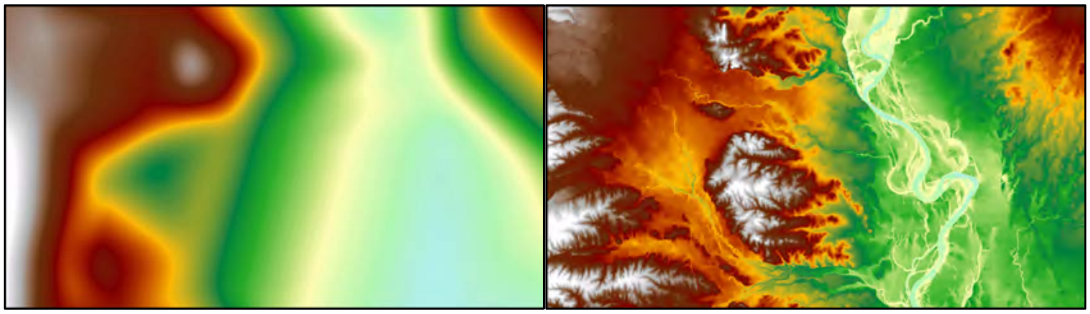

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. (Right) Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

[11] USGS Digital Elevation Model data products are described at: https://www.usgs.gov/core-science-systems/ngp/3dep/about-3dep-products-services and can be downloaded at: https://iewer.nationalmap.gov/basic/

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network. Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Subject: Comments on the Monterey Subbasin GSP

Abby and Emily,

On page 9-52, the statement below reads.

In 2020, M1W completed Phase I of the AWPF that has the capacity to produce 4,300 AFY of advanced treated water. Of this water produced, 3,700 AFY is conveyed to Seaside Subbasin for IPR use as part of M1W's Pure Water Monterey project, and 600 AFY is available to MCWD. Based on current plans, the AWPF will be expanded further to produce an additional 2,250 AFY of purified water for M1W and 827 AFY for MCWD[6].

M1W's response

M1W completed its Pure Water Monterey project and MCWD's 600 AFY yield for urban irrigation in former Fort Ord project in 2020. M1W's Supplemental EIR for the Expanded Pure Water Monterey Project increased the 3,700 AFY to 5,950 AFY that is conveyed to the Seaside Subbasin for indirect potable reuse for the Monterey Peninsula (CalAm Monterey District). The expansion will continue to provide 600 AFY to MCWD.

On Page 9-54, the statement below reads.

The current operation frequency of MCWD's production wells generally ranges from 10% to 40%. These operation frequencies are low and, barring other constraints (e.g., concerns regarding seawater intrusion), could likely be increased to an operational frequency of up to 70% to capture injected water. Additional production wells might need to be constructed to provide additional extraction capacity, depending on the volume and rate of injection. The 2020 Water Supply Augmentation Study evaluated two potential production capacities for the IPR project including 973 AFY and 2,400 AFY. The project could be readily expanded to facilitate injection of additional advanced treated water as it becomes available.

M1W's response

M1W is not aware of any future projections of MCWD wastewater flows that provide for a quantity of influent water that could be used to meet the identified yield for an expanded Ord area irrigation project or an as-yet-undefined indirect potable reuse project. Current and approved expanded facilities provide for 600 AFY total yield for MCWD. RUWAP has always been described and evaluated as a water *augmentation* project; the MCWD, FORA, and M1W approvals of RUWAP all described and evaluated that the supplies from RUWAP would *augment* groundwater supplies for the redevelopment of the former Fort Ord; the project was never described as a project to replace or reduce use of groundwater. Specifically, the RUWAP project approval in 2004 (with modifications in October 2006, February 2007, and April 2016) describe the existence of rights to groundwater from zones 2 and 2A for the benefit of the former Fort Ord and that the RUWAP adds to those volumes of water available. The Pure Water Monterey Project was approved in October 2015 and that approval included no capacity for MCWD customers. In M1W's Addendum for the Proposed Capacity Expansion from 4-mgd maximum production rate to a 5-mgd maximum production rate (dated October 2017), M1W approved providing only up to 600 AFY for urban irrigation water within the former Fort Ord. Use of MCWD wastewater flows are limited to 300 acre feet during April 1 through Sept 30 plus M1W summer wastewater rights of up to 650 AFY during May 1 through August 31. Those volumes of water do not provide the flows needed to inject water per the proposed study recommendations.

Also, as noted in the first amendment to the Pure Water Delivery and Supply Project Agreement between M1W and MCWD, Section 1.03 (a) states "Because of the uncertainty resulting from the possibility that a portion of MCWD AWT Phase 2 will be used for injection, details regarding Phase 2 implementation of MCWD's AWT Phase 2 water for injection will require a separate agreement or an amendment to this agreement based upon the existing terms of the agreement."

SUBJECT: Comments on Monterey Subbasin Public Draft GSP Appendix 6B (Monterey Subbasin Groundwater Flow Model Documentation)

Dear Mr. Breen, Ms. Gardner, and Mr. Williams:

This letter is submitted on behalf of California American Water and provides comments on Appendix 6B (Monterey Subbasin Groundwater Flow Model Documentation) for the Public Draft Monterey Subbasin GSP updated appendices released on November 10, 2021. Detailed comments are provided along with a summary of the main comments. Overall, given the number of significant deficiencies identified in these comments, the Monterey Subbasin groundwater model as currently configured does not provide reliable model results for use in GSP implementation.

DETAILED COMMENTS

Specific comments are organized by subsection with page numbers referenced below.

Section 2 (Methodology and Approach)

- Appendix 6B states the model western boundary ends at the Pacific Ocean (section 2.2.1, p. 7). **Comment: The Principal Aquifers (180-Foot Aquifer, 400-Foot Aquifer, Deep Aquifer) extend out beneath the ocean several miles beyond the Pacific Ocean shoreline. More representative model results would be obtained by extending the model domain further out beneath the ocean.**

- Appendix 6B states the model is discretized vertically into eight layers that include Layer 3 representing the Upper 180-Foot Aquifer, Layer 4 representing the 180-Foot Aquitard, Layer 5 representing the Lower 180-Foot Aquifer (Section 2.2.3, p. 8). **Comment: While this model layering may apply in the southern part of the Monterey Subbasin in the Fort Ord area, it does not apply in the northern Monterey Subbasin or the southern 180/400 Foot Aquifer Subbasin included in the model domain, where there is no aquitard within the 180-Foot Aquifer. This comment relates to the Hydrogeologic Conceptual Model (HCM) that forms the basis of the groundwater model and**

was noted in previous Hydrogeologic Working Group (HWG) comments on GSP Chapters 4 and 5 (April 5, 2021). This incorrect portrayal of the stratigraphy in the model layering in the northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin results in inaccurate model predictions in terms of groundwater levels and seawater intrusion.

- Appendix 6B states that as part of GSP development, a 3-D hydrostratigraphy model was developed to, "…provide for a more accurate representation of Principal Aquifer and Aquitard geometries and to facilitate MBGWFM grid development. The Leapfrog hydrostratigraphy model of the Basin was originally developed as part of two Airborne Electromagnetic (AEM) geophysical surveys conducted by Marina Coast Water District (MCWD) in 2017 and 2019…to help characterize seawater intrusion within the Basin." (Section 2.2.3, p. 9). **Comment: Previous HWG Comment letters (e.g., August 2018, April 2019, June 2020) have repeatedly demonstrated the significant uncertainties and flaws in the hydrostratigraphic interpretations derived from the two AEM surveys. These errors in hydrostratigraphic interpretation have been incorporated into the Monterey Subbasin groundwater model and will result in inaccurate predictions of future groundwater levels and seawater intrusion. One example of the flawed stratigraphic interpretation for the northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin is provided in Figure 2 of Appendix 6B 2, which displays a thick and continuous aquitard in the middle of the 180-Foot Aquifer and no Aquitard between the 180-Foot Aquifer and 400-Foot Aquifer. These two aquitards are misrepresented (and essentially reversed) in this area of the model domain.**

- Appendix 6B states, "…it is assumed the Deep Aquifer is not hydraulically connected to the Pacific Ocean." (Section 2.4.1, p. 12). **Comment: The lack of seawater intrusion in the Deep Aquifer at the present time is insufficient basis for adopting a No Flow boundary in the groundwater model. It is possible the Deep Aquifer is connected to the Pacific Ocean at the Monterey submarine canyon. At the very least, the Deep Aquifer likely extends out beneath the ocean floor for many miles offshore.**

- Appendix 6B describes the historical groundwater level measurements used as input for the general head boundaries on the northern edge of the model domain as including, "…seven wells in the Upper 180-Foot Aquifer (Layer 3), 12 wells in the Lower 180/400-Foot Aquifer (Layers 5 and 7)…". There is a footnote associated with this text that reads, "MCWRA water levels records classify wells in a grouped "Lower 180/400-Foot Aquifer" system, and thus specified heads from these wells were assigned to both Layer 5 and Layer 7 of the MBGWFM." (Section 2.4.2.1.1, p. 12). **Comment: This assignment of historical water levels to general head boundaries along the northern edge of the model domain is flawed for the reasons described above related to an inaccurate HCM stratigraphy. MCWRA maps of groundwater elevations clearly show distinct (different) groundwater elevations in the 180-Foot and 400-Foot Aquifers. The footnote relative to MCWRA category of wells in a "Lower 180/400-Foot Aquifer" system likely refers to wells screened in both aquifers and does not mean both aquifers have the same water levels as is assumed in the Monterey Subbasin groundwater model.**

- Appendix 6B states, "The final network of SGMA monitoring wells used for projected simulations includes seven wells in the Upper 180-Foot Aquifer (Layer 3), 10 wells in the Lower 180/400-Foot Aquifer (Layers 5 and 7)…" (Section 2.4.2.1.2, p. 13). **Comment: This assignment of future water levels to general head boundaries along the northern edge of the model domain is flawed for the reasons**

described above related to an inaccurate HCM stratigraphy. MCWRA maps of groundwater elevations clearly show distinct (different) groundwater elevations in the 180-Foot and 400-Foot Aquifers.

- In describing the southern model domain boundary of the Monterey Subbasin groundwater model, Appendix 6B describes notable differences in "hydrogeologic conceptualization and geometry between the two models that will result in imperfect matching of head conditions and unique estimates of cross-boundary flows. Notably, the Seaside Model defines aquifer units differently than the MBGWGM and includes a different number of layers." (Section 2.4.2.2.1, p. 15). **Comment: Although not described or acknowledged in Appendix 6B, this same issue of significantly different hydrogeologic conceptualization and geometry also applies along the northern model domain of the Monterey Subbasin groundwater model. This is due to the previously described flawed HCM and stratigraphy that served as the basis for model layering in northern Monterey Subbasin and southern 180/400-Foot Aquifer Subbasin.**

- Appendix 6B Table 2 provides a comparison of Seaside Model Layers to MBGWFM Layers (Section 2.4.2.2.1, p. 16). **Comment: A similar table showing the disagreement with the HCM and previous models of the 180/400-Foot Aquifer Subbasin are not provided. A table comparing the Monterey Subbasin groundwater model aquifer layers with the 180/400-Foot Aquifer Subbasin is provided below. This table shows the discontinuities and offset of aquifer units between the two subbasins, which is quite problematic for evaluation of groundwater levels and sea water intrusion between the two subbasins.**

Monterey Subbasin Aquifer Unit	**180/400 Foot Aquifer Subbasin Aquifer Unit**	**Comments**
Dune Sand Aquifer	**Dune Sand Aquifer and Perched "A" Aquifer**	**The Dune Sand Aquifer is perched and mounded on top of SVA and cannot be readily represented in MODFLOW. Appendix 6B does not explain how this unit was simulated.**
Upper 180-Foot Aquifer	**180-Foot Aquifer**	**The grouping of lower 180 and 400-Foot Aquifers in MBGWFM is inconsistent with all previous and existing models of the 180/400-Foot Aquifer Subbasin.**
Lower 180-Foot Aquifer And 400-Foot Aquifer	**400-Foot Aquifer**	
Deep Aquifer	**Deep Aquifer**	

- Appendix 6B describes how similar estimates of cross-boundary flows were obtained along the southern model domain boundary for both the Seaside Basin model and the Monterey Subbasin groundwater model (section 2.4.2.2.1, p. 16). **Comment: Similar cross-boundary flows were not obtained across the northern model domain boundary compared to the 180/400-Foot Aquifer Subbasin GSP, which was approved by DWR.**

- Appendix 6B states, "Various studies and projects have been proposed (see GSP Section 9) or are already being implemented by water management entities in both subbasin to better characterize and model local groundwater conditions and cross-boundary flows in the Laguna Seca area and across the entire Monterey-Seaside boundary." (Section 2.4.2.2.2, p. 17). **Comment: A similar statement regarding additional studies to address discrepancies in cross-boundary flows along the northern model domain boundary does not appear to be provided Appendix 6B or the remainder of the GSP.**

- Appendix 6B states, "More recent investigations of seawater intrusion conditions within the Basin…also indicate that the Deep Aquifer is not currently seawater intruded along the Monterey coastline. As such, GHB cells were assigned along the Pacific Ocean boundary for all layers in the MBGWFM apart from layer 8 (i.e., the Deep Aquifer), which was modeled as a no-flow boundary at the Monterey coastline."." (Section 2.4.2.3, p. 18). **Comment: The Deep Aquifer is certain to extend many miles out beneath the ocean, possibly ultimately outcropping in the submarine Monterey Canyon. While it would be best to extend the model domain extent out beneath the ocean, the next best choice is to assign a general head boundary. The selected choice to assign a no-flow boundary to the Deep Aquifer is flawed and is likely to result in erroneous predictions of future groundwater levels and seawater intrusion.**

- Appendix 6B describes texture maps based on borehole log lithologic descriptions for model layers 1, 3, 5, 7, and 8, which represent the various aquifers. (Section 2.5.1, p. 21). **Comment: It is just as important (maybe more important) to develop such texture maps for the aquitard model layers 2, 4, and 6, but apparently this was not done or is not presently described.**

<u>**Section 3 (Stresses)**</u>

- Appendix 6B states, "…it was assumed that 25% of total projected deliveries would be applied for outdoor uses between April – September, while the remainder of deliveries would be used to meet potable and non-potable indoor demands." (Section 3.1.2.3, p. 27). **Comment: While this assumption seems reasonable, it is inconsistent with the primary proposed future project of meeting 50% of future water demands with recycled water (see Table 8 on page 28 of Appendix 6B), which would require extensive indoor use of recycled water.**

- Appendix 6B states, "For both scenarios, pumping was distributed within individual MCWD wells based on historical monthly and total pumping rates at each well." (Section 3.2.2, p. 28). **Comment: As noted in the GSP Chapter 6 comment letter submitted on November 1, 2021, future pumping of MCWD wells based on historical pumping patterns does not accurately reflect pumping trends towards a greater amount of pumping from the Deep Aquifer.**

- Appendix 6B Table 8 (Projected MCWD Pumping Rates) shows total water demand in 2040 of 9,584 AFY with 5,495 AFY provided by recycled water and 4,089 of actual groundwater pumping. In addition, water demand is projected to increase from 3,367 AFY in 2020 to 6,001 AFY in 2025, with the vast majority of that increase being covered by increased groundwater pumping (Section 3.2.2, p. 28). **Comment: It is not clear how recycled water can realistically provide 57% of total water demand in 2040. Near term, an increase in groundwater pumping from 3,367 AFY to 5,401 AFY in 2025 is likely to exacerbate seawater intrusion that is already occurring with 3,367 AFY of groundwater pumping by MCWD.**

Section 4 (Calibration)

- Appendix 6B states that the discrepancy in cross boundary groundwater flow estimates between the Monterey Subbasin GSP and 180/400 Foot Aquifer Subbasin GSP is due to 180/400 Foot Aquifer Subbasin GSP estimates being made by non-modeling methods, and that the 180/400 Foot Aquifer Subbasin GSAs plan to do additional studies of cross-boundary flows for the 5-Year Update. It is noted that the estimates in the 180/400 Foot Aquifer Subbasin were derived from, "…aggregating data and analyses from previous reports and other available sources. No numerical modeling was completed to develop the historical or current water budget." (Section 4.4, p. 31)**. Comment: The implication of the Appendix 6B text is that the non-modeling methods of determining water budgets and cross-boundary flows must be wrong. However, water budgets are commonly done using non-modeling methods, even if ultimately being used as input to a numerical model from which the final water budget is determined. For example, the 180/400 Foot Aquifer Subbasin describes using stream gage data at multiple stations to determine streamflow percolation, which likely is better than a model estimate. Furthermore, the historical and current estimates of groundwater inflow/outflow for the 180/400 Foot Aquifer Subbasin are based in part on the Salinas Valley IGSM groundwater model. In addition, the 180/400 Foot Aquifer Subbasin GSP notes that future water budgets were based on the SVIHM groundwater model developed by USGS. Overall, both subbasins estimated groundwater inflow/outflow amounts using groundwater models.**

- Appendix 6B states that, "SVIHM does not accurately reflect hydrologic conditions in the Monterey Subbasin." (Section 4.4, p. 31)**. Comment: This statement is used to help justify Monterey Subbasin GSP cross-boundary groundwater flow estimates being more reliable than those provided in the 180/400 Foot Aquifer Subbasin GSP. However, as noted above in this comment letter and in the previous HWG comment letter on Monterey Subbasin GSP Chapters 4 and 5, the HCM used as the basis for the Monterey Subbasin groundwater model is flawed in the northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin portions of the model domain and does not accurately reflect geologic or hydrologic conditions along the northern Monterey Subbasin groundwater model domain boundary. Thus, the basis for Monterey Subbasin GSP estimates for cross-boundary flows are likely less valid than those provided in the 180/400 Foot Aquifer Subbasin GSP that has already been approved by DWR.**

- Appendix 6B states, "SVBGSA is in the process of developing a dual density groundwater model for the coastal regions of the greater Salinas Valley Basin. This model will incorporate the MBGWFM and be used to further assess volumetric exchanges between the ocean and the Salinas Valley groundwater basin. It will also aid in evaluating flows across subbasin boundaries and will be used evaluate impacts of potential regional projects that have been proposed in this GSP and other GSPs to address seawater intrusion in the Salinas Valley groundwater basin." (Section 4.4, p. 31). **Comment: Given that the MBGWFM is expected to be expanded and have uses much greater than and beyond the scope of the Monterey Subbasin GSP, it is critical that the hydrostratigraphic misrepresentation and flawed model layering (and model boundary conditions) outlined above be addressed for this broader effort (and preferably for use in the Monterey Subbasin GSP itself).**

- Appendix 6B Table 10 indicates the Normalized RMSE for Model Layer 1 is 5.7% based on a range in elevations of 198.4 feet; and that the Normalized RMSE for Model Layer 8 is 2.9% based on a range in elevations of 728.4 feet. The text states, "A generalized rule of thumb in model calibration is that the model is considered well-calibrated when the normalized RMSE is less than 10%. The low normalized RMSEs are therefore an indicator that the model is well-calibrated as a whole and within individual layers given the range of observed data." (Section 4.7, p. 33). **Comment: Review of the hydrographs indicates the range in elevations for Model Layer 1 is not more than 115 feet, resulting in a Normalized RMSE of about 10%. Even if there were an outlier somewhere in the hundreds of hydrographs provided, it would be an extreme outlier that artificially increased the range of elevations and lowered the RMSE to 5.7 %. Overall review of hydrographs indicates the calibration of the Dune Sand Aquifer is not particularly good and is no better than previous models of the area. The extreme range in elevations of 728.4 feet for Layer 8 is apparently mixing data from near the ocean in the Marina-Ord area with the highest elevations of the Corral de Tierra area, which artificially lowers the Normalized RMSE by a large amount. A more realistic groundwater elevation range of about 95 feet for the Marina Ord area for which hydrographs show an RMSE of about 14.5 feet yields a Normalized RMSE of about 15%. There was insufficient time to do similar checks on other model layers, but results for Model Layers 1 and 8 indicate a relatively poor overall calibration for the Marina-Ord area. It is also noted that while the Monterey Subbasin modeling effort appeared to use practically all available monitoring well data for model calibration (with notable exception of MPWSP data); however, the monitoring well hydrograph for MW-OU2-29-A is missing from the dataset for the Dune Sand Aquifer, which is noteworthy because it was a particularly challenging hydrograph to match with previous models.**

- Appendix 6B provides a map (Figure 29) of calibration hydrograph locations (Section 4.7, p. 33). **Comment: It is not clear why nested monitoring well data from the Monterey Peninsula Water Management Project (MPWSP) are not being used in the model calibration. These wells are located in key data gap areas of the model domain.**

<u>**Section 5 (Sensitivity and Uncertainty Analysis)**</u>

- Appendix 6B states the final calibrated Kv of Model Layer 2 was 2 x 10^{-4} ft/d (Section 5, p. 34). **Comment: A Kv of 2 x 10^{-4} ft/d is equivalent to 7 x 10^{-8} cm/s. This is an extremely low and unrealistic Kv value for a regional clay layer. Such an unrealistically low calibrated Kv value was likely driven by trying to achieve a better calibration within the overlying Model Layer 1. Previous studies indicate that accurately representing (from a hydrogeologic standpoint) the Dune Sand Aquifer (Model Layer 1) is extremely difficult because it contains perched and mounded water on top of a sloping clay layer and numerical models have trouble accurately representing such hydrogeologic conditions. The text of Appendix 6B provides no discussion of this issue and how it was addressed in the Monterey Subbasin groundwater model. The consultants that prepared Appendix 6B are quite familiar with the issue and have critiqued previous models in the area regarding this issue, yet they provide no explanation of how the issue was addressed in their own model. Regardless, it is clear from detailed inspection of calibration hydrographs for Model Layer 1 and the use of an unrealistically low Kv value for Model Layer 2 that these model challenges for simulating the Dune Sand Aquifer remain unresolved for the Monterey Subbasin groundwater model.**

Section 6 (Model Limitations and Suggested Future Refinements)

- Appendix 6B states, "…the model calibration error is within acceptable bounds…As demonstrated by the calibration error statistics summarized in Section 4.7 the MBGWFM reasonably represents historical groundwater conditions within the Subbasin using a set of parameters that are within real-world observations and established scientific principles." (Section 6, p. 35). **Comment: As discussed previously: 1) A limited review of the calibration data indicates Model Layers 1 and 8 are poorly calibrated (time did not permit for checking calibration of other model layers); 2) the HCM forming the basis for model layering and general head boundary conditions on the northern portion of the model domain are flawed; and 3) the calibrated Kv for Model Layer 2 is unrealistically low by at least two orders of magnitude. These findings indicate the statements in Section 6 about model calibration being acceptable and the model being based on realistic model parameters are inaccurate.**

- Appendix 6B notes that, "…only a small number of wells exist in the Deep Aquifers within the 180/400 Foot Aquifer Subbasin with observed water level data spanning the full duration of the historical Period. As such, simulated Deep Aquifers heads along the northern model boundary are subject to the limitations in available data to the north of the boundary, which may impact resulting calculations of 180/400 Foot Aquifer Subbasin exchanges within the water budget." (Section 6, p. 35). **Comment: It should be noted that the same limitations on available data are equally applicable south of the boundary.**

- Appendix 6B notes that there is a lack of water level calibration data outside of certain areas such as the MCWD service area and former Fort Ord Site (Section 6, p. 36). **Comment: While this statement is generally correct, there is no explanation as to why an extensive monitoring well data set for the MPWSP is not used in the model calibration – particularly given it is located in a data gap area.**

- Appendix 6B notes there is significant uncertainty with the climate change predictions provided by DWR that are the basis for future scenarios in the GSP (Section 6, p. 37). **Comment: Given the uncertainty in climate change predictions related to precipitation, it would be more prudent for future water management to assume that groundwater recharge will not increase in the future due to climate change (as has been assumed in the GSP) and assume instead it will remain consistent with historical data.**

SUMMARY OF COMMENTS

Although limited by the available time frame for review of Monterey Subbasin GSP Appendix 6B, many detailed comments are provided above. A few of the major takeaways from this review include the following:

- The HWG previously reviewed Draft GSP Chapters 4 and 5 for the Monterey Subbasin GSP and provided comments dated April 5, 2021. While the HWG comments were acknowledged as being received by the GSA, the Public Draft versions of Chapters 4 and 5 included no significant changes to the text or figures related to the HWG comments. Furthermore, these previous comments have direct bearing on the groundwater model development documented in Appendix 6B, and it is apparent that these previous HWG comments were not considered in Monterey Subbasin groundwater model development. In particular, the HCM in northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin is fatally flawed (in terms of model layering and boundary conditions) to the extent it will impact model results and lead to inaccurate future predictions of groundwater elevations and seawater intrusion in this area of the model domain.

- Although the allowed review time was insufficient to conduct a review of model calibration for Model Layers 3 through 7, review of calibration hydrographs and associated calibration statistics for Model Layers 1 (Dune Sand Aquifer) and 8 (Deep Aquifer) indicate model calibration is not within acceptable limits for the Marina Ord portion of the model domain.
- The historical challenges in achieving acceptable calibration for the Dune Sand Aquifer have not been resolved in the Monterey Subbasin groundwater model. The Kv for the underlying Model Layer 2 had to be set at unrealistically low values even to achieve the relatively poor calibration of Model Layer 1 documented in this comment letter. Utilizing a realistic Kv value for Model Layer 2 presumably would have resulted in an even worse model calibration for Model Layer 1.
- It is not clear why a No Flow boundary condition at the ocean shoreline would be used for the Deep Aquifer. This choice of boundary condition will likely lead to inaccurate future predictions of groundwater elevations and seawater intrusion.

Thank you for the opportunity to provide these comments.

Sincerely,

LUHDORFF AND SCALMANINI
CONSULTING ENGINEERS

Peter Leffler,
Principal Hydrogeologist

Supplemental Comment Letter Responses

City Of Seaside's Comments on Draft Monterey Subbasin Groundwater Sustainability Plan

"The City of Seaside received a notice dated September 20, 2021 from the Marina Coast Water District Groundwater Sustainability Agency (MCWD GSA) that they had prepared a draft Groundwater Sustainability Plan for the Monterey Subbasin (the GSP) as required by the Sustainable Groundwater Management Act (SGMA). Staff reviewed the draft Groundwater Sustainability Plan, Monterey Subbasin prepared by EKI Water & Environment, Inc. for the Marina Coast Water District Groundwater Sustainability Agency and the Salinas Valley Basin Groundwater Sustainability Agency dated September 2021 (the GSP) download from the MCWD website on October 13, 2021 from the following link https://mcwd.org/gsa gsp.html. The following comments are submitted for your consideration."

Seaside Comments	Responses
Major Comments	
1. The City of Seaside requests to be included as stakeholder (page 28)	The City of Seaside has been added to MCWD's stakeholder list and SVBGSA's Subbasin Planning Committee. Please note that the Technical Committee is formed only between the two basin GSAs to implement the GSAs' Framework Agreement.
2. The City of Seaside is requests membership in the Technical Committee (page 8-10)	See response to Comment 1.
3. Since the Framework agreement between the MCWD GSA and the SVBGSA (the Agreement) appears to give MCWD additional jurisdiction within the City of Seaside city limits beyond the MCWD GSA boundary, the Agreement should be made available for review and comment by the City of Seaside (page 12).	A copy of the Framework Agreement will be provided to the City of Seaside. It should be noted that the subject of the Framework Agreement is the responsibility for development of GSPs for the 180/400-Foot Aquifer and Monterey Subbasins.
4. The MCWD should clarify how the Water Augmentation Project would be implemented to ensure proposed development would not cause exceedances of groundwater extraction allocations (pages 6-57 and 9-31)	The environmental and feasibility assessment of the project will include an analysis of compliance with groundwater laws and with any applicable FORA water allocations.
5. The GSP should clarify how the sustainable yield would be affected by the 180/400 & the Seaside Subbasins operated under conditions similar to current conditions or probable future conditions that do not meet MT or MO boundary conditions (page 6-59).	Given SGMA requirements which apply to the 180/400 Foot Aquifer subbasin and adjudication requirements, which apply to the Seaside Subbasin, it is reasonable to assume that these basins will operate sustainability into the Future and that the 180/400 Foot Aquifer subbasin will meet MT or MO boundary conditions through voluntary or regulatory actions. Assuming otherwise leads to an infinite set of potential future boundary conditions that cannot be evaluated in the Monterey GSP.
6. The MCWD should support the Seaside Watermaster to facilitate the development of alternative water for replenishing the Seaside Subbasin to ensure that the Seaside Subbasin is able to achieve Protective Water Levels to mitigate seawater intrusion (page 9-13)	Comment noted. MCWD is collaborating with and supporting the Seaside Watermaster's groundwater monitoring and future supply projects, including future deliveries to the golf course as well as existing Ord service area customers that overly the Seaside Subbasin.
7. The GSP should clarify if Project R2, Regional Municipal Supply, is substantially different than the Regional Project as proposed by Cal Am. If not, why is "Further analysis and scoping ... needed to determine the exact location of the desalination plant, end uses, and desalination technology [9.4.2]"? If so, how are they different? (page 9-26)	As described in Section 9.4.2, this project builds upon the Seawater Extraction Barrier Project proposed in the 180/400-Foot Aquifer Subbasin GSP. This project is substantially different from the Monterey Peninsula Water Supply Project proposed by Cal Am as to source wells and desalination plant locations.
8. In Section 9.4, the GSP should tabulate the scope of and capital costs for the proposed Seawater Extraction Barrier Project (page 9-26). The scope should clarify alternatives for discharging and/or reusing extracted brackish water (page 9-28).	The scope and capital costs of the Seawater Extraction Barrier Project can be found in the 180/400-Foot Aquifer Subbasin GSP. The GSP provides a reference to that document. As discussed in Section 9.4.2.7, "the estimated capital cost for the pipeline from the wells to

Seaside Comments	Responses
	the desalination plant and desalination plant is $309,387,000. The estimated capital cost for the distribution network ranges from $65,257,000 to $84,315,000 depending on how many communities receive water. Annual operations and maintenance are projected to cost about $13,300,000". Additional analysis and refinement of the project will be conducted during the first two years of GSP implementation should the SVBGSA Board take up this project. The Seawater Extraction Barrier Project is not included in this GSP. This GSP includes the Regional Municipal Supply Project, which would treat water from the extraction barrier and deliver it for use in municipal areas.
9. It is assumed that additional investment is required to reimburse the capital expenditures and debt servicing incurred by MCWD for producing 600 AFY of recycled water. The MCWD should clarify what this investment is (page 9-58).	Language has been modified under Project M3 regarding cost to implement recycled water for irrigation.
10. Since the GSP states that potable water could be delivered to Zone 2C by direct diversion and treatment from the Salinas River during certain months with some minor permit modifications, it should also be possible to deliver irrigation water through direct diversion. This should be explored and promoted as an alternative for providing irrigation water to supplement the more expensive treated water from Pure Water Monterey (i.e., $1,100/AF versus $1,600/AF, respectively) (page 9-22)	Comment noted. The cost/benefit, timing, and priority of the proposed projects will be further analyzed during the first two years of GSP implementation.
11. Section 10.7.1, "MCWD GSA Start-up Budget and Funding to Meet Costs," should be modified to include capital projects costs which are part of the costs for implementing the GSP over the next five years and should include an estimated cost to rate payers if no grant funding becomes available (page 10-16).	It is difficult to estimate the cost to rate payers at this time since the capital projects that will actually be implemented have not been selected, are subject to environmental and feasibility studies, and may be regional in nature. In addition, development of each capital project will depend upon then available sources of funding, including grants, loans, and other sources.
Minor Comments	
Page 12. Please add "the City of Seaside" to the definition of the Marina-Ord Management Area.	Edits made.
Page 12. Since the Framework agreement between the MCWD GSA and the SVBGSA (the Agreement) appears to give MCWD additional jurisdiction within the City of Seaside city limits beyond the MCWD GSA boundary, the Agreement should be made available for review and comment by the City of Seaside.	See response to Comment 3.
Page 28. Please confirm that the City of Seaside would be included in the stakeholder database.	See response to Comments 1 and 2.
Page 55. If the "2020 UWMP anticipates that projected water demand within the entire District would be 9,584 AFY by 2040, including 2,974 AFY within the City of Marina and 6,610 AFY for the existing and future developments within the Ord Community," why is it shown as 9,300 AFY here?	9,300 AFY is the water demand projection presented in the 2020 Master Plan. It is removed from this paragraph to avoid confusion.
Page 145. The ordinate scales on the groundwater elevation graphs are too large to confirm if a linear trend line is best fit for determining trend lines. Please clarify why linear trend lines were selected to approximate groundwater elevations in the 400-ft aquifer.	Linear trends are used to predict water levels in the SMC sections. In the absence of more detailed information, use of linear trends is appropriate and generally used for such predictions.

Seaside Comments	**Responses**
Page 149. Confusion in datum for groundwater elevations. Figure 5-12 states that it is both msl and NAVD88. These are not the same datum.	The “msl” notation is a typo and removed from the figure. The datum is at NAVD88.
Page 213. Why has the inflow from Seaside Basin increased by 45% from historic to current? Is this trend expected to continue?	The increase in groundwater inflows from Seaside Subbasin is due to recent changes in groundwater gradients observed along the Seaside-Monterey boundary. Specifically, it appears groundwater level declines observed in the 400-Foot Aquifer and Deep Aquifers during the current period contribute to increased inflows from the Seaside Subbasin into the Monterey Subbasin as rates of groundwater extraction in the Marina-Ord area have not increased. Projected Model results provide estimates of potential future inflows from the Seaside Basin into the Monterey Subbasin under variable boundary conditions at the 180/400 Foot Aquifer Subbasin boundary. MTs and MOs in the Monterey Subbasin have been established to limit increases in flows across the subbasin boundary. However, as recognized in the GSP a coordinated approach between subbasins will be required to achieve sustainability in these Subbasins.
Page 215. Was annual well pumping determined from well meters (i.e. does it include non-revenue water or leakage)? If not, then that component of leakage should be omitted from the estimated recharge.	Groundwater pumping estimates were informed by (1) metered MCWD well production for the Marina-Ord area, and (2) pumping estimates provided by SVBGSA for domestic, agricultural, and municipal supply wells within the Corral de Tierra Area (Section 6.2.2). Pumping estimates provided by SVBGSA include municipal pumping data from the four water agencies within the Corral de Tierra Area (i.e., California Water Service, CalAm Toro, Hidden Hills, and Ambler Units), which were obtained directly from the Seaside Groundwater Model (see Appendix 6B). The 5% leakage factor was only applied to municipal supply pumping from these five water agencies within the Subbasin, and does <u>not</u> include unmetered pumping from domestic and agricultural wells.
Page 233. What does the following statement mean?"... fall within the middle of the range of projected boundary conditions."	Groundwater levels specified along the 180/400-Foot Aquifer Subbasin boundary under MO boundary conditions generally fall around the mid points between groundwater levels specified under the MT and SWI boundary conditions.
Page 235. Unclear. Is the assumption that the MT or MO Boundary conditions are achieved in the short term?	As described in detail in Section 6.5.1.3 and in Appendix 6B, water levels along the 180/400-Foot Aquifer Subbasin boundary are initiated at their Fall 2018 levels for all projected scenarios, gradually adjusted over twenty years to MT/MO/SWI levels, and then held constant for the remaining 30 years of the projected simulation. For the MT scenario, water levels are adjusted linearly from Fall 2018 to MT water levels over twenty years. For the MO scenario, water levels are adjusted in five-year increments based on the interim milestones (IMs) identified in the 180/400-Ft. Aquifer Subbasin GSP.
Page 238. Why is well pumping under the "No Project" scenario shown as 8,767 AFY when the MCWD UWMP estimates that the demand would be 9,584 AFY. Applying the	The 8,767 AFY estimate reflects 50-year average projected pumping rates within the Marina-Ord Area. As described in Section 6.5.1.1. and in Appendix 6B,

Seaside Comments	Responses
5% leakage rate used in this GSP indicates future pumping should be 10,088 AFY. Please clarify.	projected MCWD pumping under the “no-project” scenario follows the projected pumping demands specified in MCWD’s 2020 UWMP, where MCWD pumping is expected to increase from 3,367 AFY in 2020 to 9,584 AFY in 2040. Demand projections provided in Table 4.6 of the 2020 UWMP include a provision for loss, which is estimated to be around 5% of total demand. Thus, total projected demand estimates listed in the 2020 UWMP serve as a reasonable proxy for total projected MCWD pumping, inclusive of non-revenue water lost to leakage.
Page 243. Could groundwater extraction along the coast mitigate the inland flow of seawater? Could modeling this scenario help?	The MBGWFM currently does not simulate variable-density groundwater flow nor does it simulate groundwater flow in adjacent subbasins, (see Appendix 6B), thus making a detailed analysis of seawater intrusion mitigation strategies is impractical. However, as described in Section 9.8.6*,* SVBGSA in coordination with MCWD plans to create a variable density model for the coastal region of the greater Salinas Valley Groundwater basin that incorporates the MBGWFM within the first 5-years of SGMA implementation. A more detailed analysis of seawater intrusion mitigation strategies will be completed upon development of this model.
Page 244. Should modeling be performed to predict scenarios, under which MCWD alters pumping regime to minimize seawater intrusion?	See response to comment re: page 243 above.
Page 245. What causes groundwater elevations to instantaneously increase by 2 feet under the no project condition?	It is a result of model simulation and likely due to that the first two years of the analog period are wet years, as can shown by the similar patterns observed around years 2038 and 2058.
Page 245. How was the MO of approximately 7-ft increase determined?	The 2004 average groundwater level was about 7 ft higher than the 2018 average groundwater level.
Page 245. How was the MT of 2-ft increase determined?	The 2015 average groundwater level was about 2 ft higher than the 2018 average groundwater level.
Page 248. Is this correct? Outflow from the 180/400 Subbasin are affecting the Monterey Subbasin?	Yes, given their demonstrated hydraulic connectivity, interactions between subbasins are affecting the sustainability of other subbasins.
Page 250. Note (c) is missing.	Reference to note (c) is a typo and is deleted.
Page 250. Table 6-5 (No Project Condition) shows outflow to 180/400 Subbasin at 3,849 AFY and 1,927 AFY for MT and MO boundary conditions, respectively. Table 6-8 (Project Condition) shows 6,833 AFY and 4,901AFY respectively. This appears to indicate that the MT and MO boundary conditions to the 180/400 Subbasin are attained at significantly different times or are different for the "No Project" and "Project" scenarios. This appears to also be the case for inter-basin transfer to the Seaside Basin. Can this be better explained?	See response to comment re: page 235 above. For all scenarios, water levels are initialized at Fall 2018 conditions along the 180/400-Foot Aquifer Subbasin Boundary, gradually adjusted to reach MT/MO/SWI levels over 20 years and are then held constant over the remaining 30 years of the simulation. Similarly, for all scenarios, water levels along the Seaside Subbasin boundary are held constant at Fall 2017 levels simulated from the Seaside Model, or at MT water levels specified for Corral de Tierra wells in the Laguna Seca area (see Section 6.5.1.3 and Appendix 6B). There are no changes in boundary condition assumptions between the “project” and “no project” scenarios. Rather, implementation of the “project” scenario results in higher water levels within the Monterey Subbasin relative to the “no project” scenario, thus impacting cross-boundary flow estimates with the adjacent subbasins.

Seaside Comments	Responses
Page 250. Table 6-5 (No Project) shows well pumping at 8,767 AFY for MT and MO boundary conditions. Table 6-8 (Project) shows 4,488 AFY for MT and MO boundary conditions. Does the model account for variability in pumping conditions since the Water Augmentation project would not come on-line for at least 6 years (see Fig. 9-6)? That is, what would cause and when would pumping exceed 4,488 AFY under the "Project" Conditions?	Yes, see slide #20 on stakeholder presentation #5.
Page 250. Do the future pumping rates shown in Table 6-8 account for leakage?	Yes.
Page 251. Are the increases in groundwater elevations shown here mostly attributed to actions performed, and MTs and MOs achieved, in adjacent subbasins?	That is correct.
Page 252. It appears that this report is stating that if the adjacent subbasins are no operated sustainably, then the Monterey Subbasin could not be managed sustainably?	Since the Monterey Subbasin is interconnected with adjacent subbasins, the sustainability of one subbasin is dependent on other basins also achieving sustainability.
Page 252. The groundwater levels appear to stabilize within the first 10 years due to assumed actions in adjacent subbasins. It could be important to consider the effects on water budget for scenarios where the adjacent subbasins are not operated under MT and MO boundary conditions.	See response in Comment #5.
Page 253. It is unclear how the range of 4,400 to 9,900 AFY was determined? Above the report states that 2,714 AFY is the lower limit of the range and Table 6-5 suggests that 8,767 AFY is sustainable if MOs are achieved.	This paragraph discusses the future sustainable yield of the Marina-Ord Area WBZ which are based on the “no project” scenario analysis (Section 6.5.4) and the “project” scenario analysis (Section 9.6.1). These results show that groundwater levels stabilize during the 30-year GSP implementation period when average rates of extraction are 4,376 AFY for the “project” scenario and 9,870 AFY for the “no project scenario”. This range of values is identified as the potential future sustainable yield of the Monterey Subbasin as MTs and in some cases MOs are achieved in RMS wells at these rates of extraction, under variable boundary conditions and climate scenarios. The projected sustainable yield is not the same as the historical sustainable yield (2,714 AFY) because it takes into account future conditions including variable climate and boundary conditions. The variable boundary conditions assume that adjacent subbasins will also achieve sustainability into the future.
Page 256. Is there a discontinuity in the modeling geometry at the interface of the Seaside Basin and MBGWFM? If so, how can this be rectified?	As described in detail in Appendix 6B, there are notable differences in hydrogeologic conceptualization and geometry between the MBGWFM and the Seaside Model that will result in imperfect matching of head conditions between the two models. As such, a few simplifying assumptions had to be made to effectively link head outputs from the Seaside Model to general head boundary cells along the Seaside boundary within the MBGWFM. This was done in a manner that results in very similar estimates of total historical cross-boundary flows between the two models (i.e., within 2% on average). MCWD encourages continued collaboration with the Seaside Basin to further rectify the discrepancies between the two models in a future

Seaside Comments	Responses
	update to the MBGWFM, and/or to integrate both models into a regional model that covers both subbasins.
Page 311. Based upon Table 6-4, it appears that sustainability goal can be achieved mostly by inter-basin coordination.	Yes
Page 312. How will Seaside Watermaster Actions be supported?	As discussed on page 311 (Section 8.2), these projects and actions are further described in Chapter 9. Please see Section 9.5.1 for further details.
Page 315. The City of Seaside or the Seaside Watermaster should consider requesting membership in the Technical Committee.	See response to Comment 2.
Page 316. Why was 2004 groundwater elevation used for this MO?	See Section 8.7.3.1.
Page 329. Are the MT and MO for the 180/400 Subbasin approximately-8 and -3.4 near Well MW-B-05-180? If not, why are -8 and-3.4 the MT and MO for this well?	As described in Section 6.1.5.3 and in Appendix 6B, MT and MO water levels were assigned to general head boundary cells along the northern MBGWFM boundary using the closest representative monitoring well (RMW) to each cell in the 180/400 Foot Aquifer Subbasin SGMA monitoring network. In the vicinity of Well MB-B-05-180, MT and MO water levels at the northern boundary were informed by RMW 14S02E27A001 in the 180/400-Foot Aquifer Subbasin. At this RMW, the MT is set at -9.9 ft msl, and the MO is set at -3.1 ft msl, which is very close to the MT/MO defined for Well MW-B-05-180. The MT and MO were set at Well MW-B-05-180 per its historical water levels using the same methodology as outlined in Section 8.7.3.1.
Page 329. 1992 to 1998 data for MW-OU2-29-180 and MW-B-05-180 seem to be skewed and may need to be ignored when determining MT and MO.	Water levels have been relatively stable in these wells and the changes since 1992 are relatively minor (i.e., within 2 ft).
Page 330. Is this one outlier determining the MT of-13.3 for MP-BW-42-295. (see MT-10 for adjacent Well MW-OU2-66-180).	The MT and MO in Well MP-BW-42-295 were set using the same methodology in Section 8.7.3.1, and the water levels at this well have been relatively stable.
Page 335. Setting the MTs to 2015 groundwater elevations seems to contradict the goal of preventing seawater intrusion.	See Section 8.7.3.1.
Page 342. Can the following statement be clarified to state whether the proposed MTs and MOs help Seaside Basin obtain its adjudication requirements: "Monterey Subbasin minimum thresholds do not prevent the Seaside basin from meeting its adjudication requirements, including the occurrence of Material Injury."	This statement was added per the request of the Seaside Watermaster. Since the Seaside Subbasin is not subject to SGMA, there are no direct SMCs established in the Seaside Subbasin that can be compared to those defined in the Monterey Subbasin. However, the GSAs will work with the Seaside Watermaster to meet
Page 392. Should a column be added to Table 9-1 for"...a description of the measurable objective that is expected to benefit from the project or management action [354.44(a)(l)"? If not, is this information given elsewhere?	The information can be found in sections “Expected Benefits and Evaluation of Benefits” under each project.
Page 394. If the extraction barrier is a necessary component of Project R2 (see Section 9.4.2.7 which states it is a precursor), should it be included here? If not, why is the seawater extraction barrier not included as a separate project in Table 9-1?	See response in Comment #8.
Page 394. Please confirm estimated cost of $172M for R1 (Section 9.4.1.7 seems to indicate $181M)	Edited to $181M.
Page 396. The costs for pilot scale modeling should be moved from Project M4 to Project M3.	The bench scale pilot testing is associated with the monitoring well(s), data gaps filling, project. Thus, the GSAs intend to keep it in Project M4.

Seaside Comments	Responses
Page 396. The demand for 1,427 AFY irrigation water at a unit production cost of $1,600/AF seems high. Section 9.4.6.7 states "MCWD's 2020 UWMP estimates that 950 AFY of landscape irrigation demand can be met by recycled water by 2030 and 1,270 AFY by 2040".	Delivering 1,427 AFY of recycled water to MCWD for irrigation will likely require an expansion of the M1W AWPF. Cost and benefits of the proposed projects will be further refined during the first two years of GSP implementation.
Page 398. Should the costs shown here only reflect costs to the MCWD GSA?	Total implementation costs are presented. In many cases, these costs reflect overall costs to both MCWD and SVBGSA.
Page 398. The Seaside Watermaster supports the construction of a facility that would allow water to be imported and injected into the Seaside Basin (see letter to M1W et al dated May 24, 2021). Can this section be clarified to state potential actions that will be implemented by the GSA to support the Seaside Watermaster desire to import water?	This level of detail is not included within the GSP, but will be identified in future updates. MCWD is collaborating with and supporting the Seaside Watermaster's groundwater monitoring and future supply projects, including future deliveries to the golf course as well as existing Ord service area customers that overly the Seaside Subbasin.
Page 399. Should the costs shown here only reflect costs to the MCWD GSA?	See response to comment re Page 398 above.
Page 399. Projects I5 and I6 appear to be the same action. Please clarify how one could be implemented without the other.	Project I5 includes a working group of multiple agencies and stakeholders to develop consensus on the current understanding of seawater intrusion, and the development of a plan to address seawater intrusion. Project I6 is being lead by the SVBGSA and MCWD and includes the development of numerical variable density groundwater model that will aid in modeling seawater intrusion within the Monterey Subbasin and the coastal regions of the Salinas Valley Groundwater basin. This model will be used to evaluate the efficacy of potential projects identified by the SWIG to address seawater intrusion.
Page 399. Please consider adding an action that supports modeling integration with Seaside Subbasin.	The numerical variable density groundwater model being developed for the coastal regions of the Salians Valley Groundwater Basin, will incorporate the Seaside Subbasin.
Page 400. Should Project I9 be modified to include wells that become non-productive due to such things as high TDS?	There are currently no domestic wells near the coast within the Monterey Subbasin.
Page 403. Section 9.4 would be more readable if the organization of project descriptions followed Table 9-1 and used the P/MA # found there.	P/MA # added to section titles.
Page 407. Does the FORA HCP have water rights and flow prescriptions for the Salinas River?	It does not.
Page 407. Since the GSP states that potable water could be delivered to Zone 2C by direct diversion and treatment from the Salinas River during certain months with some minor permit modifications, it should also be possible to deliver irrigation water through direct diversion. Should this be explored and promoted as an alternative for providing irrigation water to supplement the more expensive treated water from Pure Water Monterey (i.e. $1,100/AF versus $1,600/AF, respectively)?	See response to comment 10 under Major Comments.
Page 411. Where is the scope of work and capital costs described for the Seawater Intrusion Extraction Barrier Project?	See response to Comment 8 under Major Comments.
Page 411. Project R2 states ''The plant will produce approximately 15,000 AFY of potable water for use." Chapter 6 states that there is approx increased demand of 5,300 AFY. Why is desal plant being proposed that could provide almost 3 times the future demand?	The desalination plant is conceptualized as a regional project that may provide water to multiple subbasins including the 180/400-Foot Aquifer Subbasin and the Monterey Subbasin.

Seaside Comments	Responses
Page 411. Is Project R2 substantially different than the Regional Project as proposed by Cal Am? If not, why is "Further analysis and scoping ... needed to determine the exact location of the desalination plant, end uses, and desalination technology"? If so, how are they different?	See response to comment 7 under Major Comments.
Page 411. Table 9-1 does not include "Priority Project 6." Please clarify where this project is tabulated.	See response to Comment 8 under Major Comments.
Page 412. Please clarify how extracting an additional 35,000 AFY from the basin reduces groundwater extraction and will "either raise groundwater elevations or reduce the rate of groundwater elevation decline over time."	The Regional Municipal Supply Project (Project R2 in Chapter 9), was originally developed in the 180/400-Foot Aquifer Subbasin GSP. The purpose of extracting intruded seawater is to both prevent further intrusion as well as move the leading edge seaward by affecting the gradients in the vicinity of the extraction barrier. The extraction barrier works best in conjunction with other projects that can use the extracted and desalted water for in-lieu use, direct delivery, or injection, as described in the GSP. This GSP includes the Regional Municipal Supply Project, which would treat water from the extraction barrier and deliver it for use in municipal areas. By providing water for direct delivery, it would act as in lieu recharge through reducing the amount of groundwater that would need to be extracted. By reducing extraction, it would support raising groundwater elevations or reducing the rate of groundwater elevation decline over time.
Page 412. Please clarify if the extraction wells are extracting 100% seawater. If not, how is this project able to reduce groundwater extraction.	The exact location of the wells has yet to be determined; however, the conceptual design of this project is to draw brackish water such that it forms a hydraulic barrier to further seawater intrusion.
Page 412. Please clarify how extracting water from the basin will reduce any potential for land subsidence.	Using desalinated water instead of pumped groundwater leaves water in the ground and prevents risk for land subsidence.
Page 412. Please clarify" This would reduce groundwater extraction by that amount, increase the Subbasin's groundwater storage." Unless the extraction wells are pumping 100% seawater, there is not a one-for-one benefit for reduction in groundwater extraction	The extraction barrier and desalted water for other uses addresses seawater intruded groundwater and provides an alternative supply, thereby allowing for more groundwater to stay in the aquifers. There may not be a one-for-one benefit, but that is not the purpose or promise of the project.
Page 413. Please clarify alternatives for discharging and/or reusing extracted brackish water. If none, please clarify if there are potential cost effective alternatives to Project R2.	There are two options for the brackish water: discharge to the ocean or treat for beneficial use. The costs/benefits of various technologies and discharge options will be further analyzed during implementation should the SVBGSA Board take up this project.
Page 416. Please clarify where this cost data is derived from.	This project is still conceptual and cost estimates will be refined with further project scoping.
Page 417. Why is the seawater intrusion extraction barrier project not better described in this section?	See response to Comment 8 under Major Comments.
Page 440. Please clarify how IPR would increase groundwater elevations.	IPR provides in-lieu recharge benefits that would reduce MCWD’s groundwater pumping.
Page 440. Since Project M3 is not a supplemental water supply project, it is unclear how it would "add" water to the aquifer for future development? Please clarify.	Project M3 is a water augmentation project that does provide additional water to meet water demands within the Subbasin and reduce reliance on groundwater.
Page 443. Have all the capital expenditures been paid for the 600 AFY? If not, please clarify the investment needed to reimburse the capital expenditures and debt servicing for the 600 AFY.	Language has been modified under Project M3 regarding cost to implement recycled water for irrigation.

Seaside Comments	**Responses**
Page 443. Please clarify if the "soft costs" provided here include debt servicing. If not, whv not?	Language has been modified under Project M3 regarding cost to implement recycled water for irrigation.
Page 445. Please confirm that RUWAP pipe extends south of Coe Ave in GJM Blvd.	Yes. It extends to near South Boundary Road in GJMB but is not constructed within South Boundary Road (the portion that heads east at the southern part of the diagram). The extension of the recycled line down South Boundary road is planned but not yet constructed.
Page 487. Can the Monterey Subbasin Model be coordinated with the Seaside Basin model to simulate conditions across the subbasins?	See response to comment re: page 256 above. MCWD encourages continued collaboration with the Seaside Basin to further rectify the discrepancies between the two models in a future update to the MBGWFM, and/or to integrate both models into a regional model that covers both subbasins.
Page 491. Addressing potential overdraft could be managed by producing documents such as a monitoring and management plan and a management action plan that addresses policies and procedures to monitor and respond to water elevation concerns.	Comment noted.
Page 497. Can extraction wells be added to the monitoring network?	They can be added to the seawater intrusion monitoring network. However, extraction wells are generally not included as part of part of the groundwater elevation monitoring network, because of the variability in water levels caused by extraction.
Page 497. The annual report could also address if milestones and goals are being attained and, if necessary, potential corrective actions that may be employed to respond to deviations from goals.	Comment noted.
Page 507. What is the estimated additional costs to rate payers if no grant funding becomes available?	See response to Comment 11 under Major Comments.
Page 508. Please clarify why Administration and Legal costs are 30% of the total cost.	This category includes District staff time.

4/5/2021 – HWG COMMENTS ON DRAFT MONTEREY SUBBASIN GROUNDWATER SUSTAINABILITY PLAN, CHAPTERS 4 AND 5

The Hydrologic Working Group (HWG) was formed pursuant to a 2013 Settlement Agreement associated with California American Water Company (CalAm) Monterey Peninsula Water Supply Project (MPWSP)[1]. *The HWG consists of Mr. Martin Feeney and Mr. Tim Durbin who represent the Salinas Valley Water Coalition (SVWC) and Mr. Peter Leffler and Dr. Dennis Williams who represent CalAm*[2]*. CalAm and SVWC are parties to the Settlement Agreement*[3]*. The HWG serves as an internal peer review group to evaluate data and analyses and prepare investigation documents associated with the MPWSP.*

The MPWSP is being implemented by California American Water Company (Cal Am) to increase water supply for its customers on the Monterey Peninsula. The MPWSP includes construction of slant wells that will extract a total of approximately 15.5 million gallons per day of groundwater and seawater as part of the intake system for a desalination plant[4]. The Slant wells are located in the 180/400 Foot Aquifer Subbasin, approximately 2/3 mile north of the Monterey Subbasin. The MPWSP does not provide any water to residents or other water users within the Monterey Subbasin. Concerns have been raised by Marina Coast Water District and others that the Slant wells will extract groundwater and impact groundwater quality within the Monterey Subbasin[5]. The MPWSP is currently the subject of litigation.

As indicated above, the HWG is funded by Cal Am and the SVWC, proponents of the MPWSP. The majority of the comments provided by HWG focus on conditions in the vicinity of the MPWSP, and reflect HWG's opinions regarding conditions within the Monterey Subbasin, which support the HWG's position that the MPWSP will not withdraw or degrade groundwater quality within the Monterey Subbasin[6]. A long record of comments and responses associated with the MPWSP exist but are not included herein.

The Monterey GSP does not address the potential impacts of the MPWSP on groundwater within the Monterey Subbasin. The Monterey Subbasin GSP focuses on basin sustainability and identifying projects and management actions that will bring the basin to sustainability. Given that the MPWSP is not located within the Monterey Subbasin nor will it provide water to entities within the Monterey Subbasin it is not analyzed in the GSP. Hydrogeologic conditions in the 180/400 Foot Aquifer Subbasin and in the vicinity of the MPWSP are discussed in the two GSPs that have been prepared for the 180/400 Foot Aquifer Subbasin including:

- Salinas Valley Groundwater Basin 180/400 Foot Aquifer Subbasin Groundwater Sustainability Plan, prepared by Montgomery Associates, dated 3 January 2020 (180/400 Foot Aquifer Subbasin GSP).
- Groundwater Sustainability Plan for the Marina GSA Area of the 180/400 Foot Aquifer Subbasin, prepared for the City of Marina Groundwater Sustainability Agency Marina CA, dated January 2020 (Marina GSA Area of the 180/400 Foot Aquifer Subbasin GSP).

If the MPWSP is implemented, its impacts on groundwater quality and sustainability within the Monterey Subbasin will be assessed consistent with long-term management and monitoring conducted pursuant to the GSP. Such monitoring

FEIR, Appendix E3.

[4] This information is based on the recovery rate of 42% cited on page 3-58 of the FEIR, which also states that 24.1 MGD of source water would be required to produce 9.6 MGD of desalinated water.

[5] FEIR, Chapter 8

[6] FEIR, Chapter 8

will be critical as the FEIR did not consider the potential impacts of SGMA[7] on future basin conditions and considered any potential changes to inland hydraulic gradients, which are causing seawater intrusion within the Salinas Valley Groundwater Basin (SVGB), as "speculative". Although the life of the MPWSP is assumed to extend well beyond 2041 when sustainable groundwater basin management is required under SGMA, the California Public Utilities Commission (CPUC)[8] concluded the following when approving the MPWSP:

> *Comments assert that the Final EIR/EIS fails to consider that future groundwater projects and those proposed as part of SGMA could restore groundwater levels in the SVGB and ultimately raise groundwater levels enough to flatten or reverse the inland groundwater gradient. It would realistically require decades of groundwater management to flatten the groundwater gradient, much less reverse it, and expectations that groundwater projects would be successful in affecting the inland gradient within the life of the MPWSP would be overly optimistic. There are no reasonably foreseeable cumulative projects proposed to reduce or reverse the current landward gradients in the Dune Sands and 180-Foot aquifers at this time, and while projects under the SGMA may improve the sustainability of the SVGB -- such as a basin-wide reduction in pumping, and/or increased recharge necessary to fill the groundwater depression on the east side of Salinas, and/or projects that may involve increasing protective groundwater elevations along the coast (much like CSIP) or include extraction systems to capture incoming seawater intrusion along the coast at CEMEX (much like the proposed MPWSP) -- such actions or projects are too speculative to assume and opine about in the EIR/EIS.*

HWG Comments	Responses
Chapter 4 – Hydrogeologic Conceptual Model	
1. The GSP states, "The geology described here is based on previously published scientific reports from investigations conducted by the USGS, State of California, other consulting firms, and academic institutions."(Section 4.1.1, Geological and Structural Setting, p. 64). **HWG Comment:** We note that extensive field work conducted by the HWG between 2013 and 2018, including test slant well installation/testing, drilling of several borings and installation of an extensive monitoring well network, extensive data analyses covering the coastal southern 180/400-Foot Aquifer Subbasin and coastal northern Monterey Subbasin are documented in publicly available reports prepared by the HWG and posted on the Monterey Peninsula Water Supply Project (MPWSP) website (e.g., HWG, November 2017). These HWG	The GSP incorporates information developed as part of the Monterey Peninsula Supply Project (MPWSP), to the extent that it is relevant to the GSP. However, the 8 well clusters completed as part of the MPWSP focused on the area of the MPWSP and are all located within the 180/400 Foot Aquifer Subbasin. None of these wells are located within the Monterey Subbasin, nor is the MPWSP the focus of this GSP. The data gathering and DMS construction for the Monterey Subbasin include: • > 100,000 water level & water quality records from > 1000 wells • Lithology & well construction from > 2,000 wells • MCWD production well data (20 years) • Airborne Electromagnetic Surveys (2017 – 2019)

[7] Page 8.5-635 of the FEIR states: "Actions that may be developed or required as a function of SGMA are too speculative to opine about in the EIR/EIS. Nonetheless, as demonstrated above, substantial actions would be needed merely to arrest seawater intrusion, without consideration of more dramatic actions that would be needed to reverse such intrusion.

… the expectation that the groundwater depression on the East Side will be resolved within a reasonable timeframe and the inland gradient would be dramatically decreased is speculative for the reasons explained above, and the impact conclusion on groundwater resources remains unchanged.

[8] 12 September 2018 Memorandum RE: Responses to Comments Received after Publication of the MPWSP Final EIR/EIS to Commissioners and ALJs From: John E. Forsythe- Energy Division MPWSP CEQA/NEPA Team CPUC Legal Division. page 18.

HWG Comments	Responses
documents incorporated data from previous studies by others (many of which are cited in the Monterey Subbasin GSP), and allowed for improved hydrogeologic interpretations by incorporating both existing and new field data collected by HWG. The Monterey Subbasin GSP ignores these HWG documents and makes geologic interpretations that are inconsistent with the most recent data that has been collected. Some of the specific inconsistencies are noted in other comments in this letter.	• Numerous publicly available field studies water level/quality data/hydrogeologic investigations, ect. These data have been used in combination to develop the Geological and Structural Setting presented in the Monterey Subbasin GSP.
2. The GSP mischaracterizes the Dune Sand Aquifer in multiple instances in Chapter 4. One example is the attempt to label the Dune Sand Aquifer as a "Principal Aquifer" (Section 4.2.1, Hydrogeology in the Marina-Ord Area, Table 4-1, page 79). **HWG Comment:** The Dune Sand Aquifer is not a Principal Aquifer in the subbasin. The Draft GSP prepared by City of Marina (2019) stated the Dune Sand Aquifer, "…is not commonly used for drinking water or agricultural irrigation". The Monterey County Water Resources Agency (MCWRA), which has studied and characterized the groundwater basin for many decades, does not consider the Dune Sand Aquifer as a principal aquifer (e.g., no seawater intrusion maps are prepared for the Dune Sand Aquifer by MCWRA). The 180/400-Foot Aquifer Subbasin GSP, which the MCWD GSA adopted and submitted to DWR, also does not classify the Dune Sand Aquifer as a Principal Aquifer. The Dune Sand Aquifer is not a Principal Aquifer due in part to its lack of capability for use in groundwater production (e.g., thin saturation, groundwater quality issues related to sea water intrusion and nitrates, etc.). In addition, the Hydrogeology section for the Corral de Tierra Area in Monterey Subbasin GSP Chapter 4 states that following about the upper 120 feet of sediments, "Several small domestic wells draw groundwater from these local alluvial aquifers, but these volumes of groundwater are minimal…Since this volume of groundwater is neither economic or significant, these shallow sediments are not considered a principal aquifer…Groundwater in these sediments is hydraulically connected to the	The Dune Sand Aquifer readily meets the definition of Principal Aquifer under SGMA. The California Code of Regulations Section 351 defines a Principal Aquifer as follows: *"Principal aquifer" refer to aquifer or aquifer systems that store, transmit and yield significant or economic quantities of groundwater to wells, springs, or surface water systems*. Areal recharge is the primary source of freshwater to the Monterey Subbasin. The Dune Sand Aquifer is the upper most aquifer within the Marina Ord Area and is made up of highly permeable Older Dune Sand and Dune Sand Deposits. It extends across over 1/2 of the Marina Ord Area, where it has been identified as a Principal Aquifer (see Figure 4-2 Monterey GSP[9]). It is highly permeable and stores, transmits, and yields significant quantities of groundwater to other aquifers within the Monterey Subbasin from which groundwater is withdrawn. The absence of drinking water wells or agricultural wells within this aquifer does not diminish its importance to the Monterey Subbasin, nor preclude it from being characterized as a Principal Aquifer within the Monterey Subbasin pursuant to SGMA. The extent of surficial Dune Sand Deposits which have high recharge potential are identified on geologic and hydrologic soil group maps presented on Monterey GSP Figure 4-2 and Figure 4-7. Fort Ord Monitoring wells, shown on Figure 3-9 show that these Dune Sand Deposits are saturated over a significant portion of the Marina Ord Area and make up the Dune Sand Aquifer. The Dune Sand Aquifer does not exist in the Corral de Tierra Area as discussed in Monterey GSP Section 4.2.2, therefore references by the HWG regarding properties of this aquifer within that area appear to be

[9] Figure reference numbers and section numbers within this response to comments are based on:

- Monterey GSP Chapter 5 published Draft, dated 4 January 2021

HWG Comments	Responses
small streams found in the area…" (page 111 of Chapter 4). This conclusion for the Corral de Tierra Area is inconsistent with designating the Dune Sand Aquifer, which cannot even claim to be tapped by "several small domestic wells", as a Principal Aquifer. As noted above, designation of the Dune Sand Aquifer as a Principal Aquifer is inconsistent with the 180/400-Foot Aquifer Subbasin GSP (where the Dune Sand Aquifer also is present), which specifically did not designate the Dune Sand Aquifer as a Principal Aquifer. It is also important to point out that the Dune Sand Aquifer, as defined in the Monterey Subbasin GSP, consists of two distinct aquifers – the coastal Dune Sand Aquifer that directly overlies the 180-Foot Aquifer and the perched/mounded Dune Sand Aquifer (known as the A-Aquifer in Fort Ord studies) that overlies the Fort Ord Salinas Valley Aquitard (FO-SVA) clay layer (incorrectly referred to as Salinas Valley Aquitard in the Monterey Subbasin GSP). The coastal Dune Sand Aquifer is intruded with sea water, while the perched/mounded Dune Sand Aquifer is perched in areas, has thin saturation, is impacted by nitrates, and is not developed with production wells for any significant water supply uses.	misinterpreted. Further, the Dune Sand Aquifer does extend north of the Salinas River within the 180/400 Foot Aquifer Subbasin (See Monterey GSP Figure 4-2). Therefore, it is not inconsistent or surprising that the Dune Sand Aquifer was not identified as a Principal Aquifer in 180/400 Foot Aquifer Subbasin, the majority of which lies north of the Salinas River. The geology and extent of the Dune Sand Aquifer within the Monterey Subbasin is described in detail in Monterey GSP Section 4.2.2.1. The understanding of the Dune Sand Aquifer in the Monterey Subbasin is based upon hundreds of monitoring wells installed in this aquifer and deeper aquifers across the Marina Ord Area (see Monterey GSP Figure 3-9). The majority of these wells have been installed by the Army to characterize the stratigraphy and water quality of this aquifer and facilitate remediation of chemicals historically released at Fort Ord. Over 200 Million dollars has been spent by the Army to characterize the Dune Sand Aquifer and the underlying Upper 180-Foot Aquifer and clean up chemical impacts to groundwater within these aquifers. This fact alone should highlight the importance of these aquifers. Understanding the interdependence of these aquifers with groundwater resources within the Monterey Subbasin is critical to the GSP and long-term management of the groundwater basin.
3. The GSP relies on old geologic cross-sections from 2001 (Section 4.2.1.1, Cross-Sections, pages 8085). **HWG Comment:** The cited geologic cross-section references and Figures 4-9 through 4-12 do not utilize best available science and most recent borehole and geophysical logs for wells drilled in the area, nor do they utilize the most recent geologic cross-sections developed based on these data (see HWG, November 2017). This results in mischaracterization of hydrogeologic conditions for the GSP Plan Area. Geologic cross-sections that use the latest available data and include areas within the Monterey Subbasin are provided in previously published HWG documents (HWG, November 2017; HWG et al., February 2020).	The geologic cross-sections included in the GSP are basin-wide sections that incorporate substantial data that has been developed over time within the Plan Area. These boring logs do not include information from all of the wells and borings located within the Subbasin or adjacent subbasins. The 2017 borehole and geophysical logs completed as part of the MPWSP and referenced by the HWG focus on the area of that project. The MPWSP nor these boring logs are located within the Monterey Subbasin and are not the focus of the Monterey Subbasin GSP. Information from these wells was incorporated into the GSPs prepared for the 180/400 Foot Aquifer Subbasin.
4. With regard to the Dune Sand Aquifer, the GSP states, "The aquifer is perched further away from	There is no guidance or regulation under SGMA that would suggest that a Principal Aquifer cannot be perched in some areas.

HWG Comments	Responses
the coast in areas where the SVA exists… " (Section 4.2.12, Principal Aquifers, page 86). **HWG Comment:** The HWG agrees with this GSP statement about the Dune Sand Aquifer being perched in areas where it is underlain by the SVA (more correctly referred to as the FO-SVA). However, perched aquifers should not be designated as Principal Aquifers as is being done in the Monterey Subbasin GSP.	
5. The GSP refers to an average saturated thickness of the Dune Sand Aquifer being approximately 50 feet (Section 4.2.12, Principal Aquifers, page 86). **HWG Comment:** As described above, there are two distinct aquifers being referred to collectively in the GSP as the Dune Sand Aquifer. While the coastal DSA may have a saturated thickness of 50 feet or more in some areas, the perched/mounded DSA has a saturated thickness considerably less than 50 feet.	There is only one Dune Sand Aquifer that has been defined within the Monterey Subbasin. The groundwater levels presented on Monterey GSP Figures 5-1 and 5-5 show the hydraulic gradient mapped in the Dune Sand Aquifer, which is consistent with groundwater maps and interpretations developed by the Army as part of remedial efforts at Fort Ord. The groundwater gradient presented on these maps is consistent with chemical migration patterns also monitored at Fort Ord. The saturated thickness of the Dune Sand Aquifer does vary across the Monterey Subbasin. Groundwater elevation information and estimate specific yield indicates that approximately 30,000 AF to 60,000 AF of groundwater are stored within the Dune Sand Aquifer within the Marina Ord Area (Section 8.8.3.1).
6. The GSP does not distinguish and describe the differences between the Salinas Valley Aquitard (SVA) and Fort-Ord Salinas Valley Aquitard (FO-SVA) and its significance to the perched/mounded aquifer (underlain by FO-SVA) versus the Dune Sand Aquifer and its equivalents (not underlain by FO-SVA) in many places in the document (Chapter 4). **HWG Comment:** It should be noted that the SVA and FO-SVA are not the same aquitard and FO-SVA occurs at a higher elevation; therefore, they should not be referred to as the same aquitard.	The GSP does distinguish between the FO-SVA and the SVA and describes the relationship between these aquitards. Please see discussion in Monterey GSP Section 4.2.2.1.2. Fort Ord-Salinas Valley Aquitard.
7. The GSP shows a Conceptual Site Model diagram that was developed from Fort Ord studies, and implies that the Fort Ord Conceptual Site Model diagram applies throughout the Monterey Subbasin (Section 4.2.1.2, Principal Aquifers, Figure 4-13, p.87). **HWG Comment:** Recent studies completed by the HWG demonstrate that the Fort Ord Conceptual Site	Section 4.2.2 clearly states that the conditions in the Marina-Ord Area do not extend throughout the of the Monterey GSP, and different principal aquifers are present in the Corral De Tierra Area. The Monterey GSP also does not evaluate or draw conclusions regarding conditions in the southern portion of the 180/400 Foot Subbasin. However, as shown on Figure 3-9, hundreds of wells have been installed at the northern portion of the Monterey Subbasin, which have been used to characterize conditions in this area

HWG Comments	Responses
Model does not apply in the southern portion of the 180/400 Foot Aquifer Subbasin or the northern portion of the Monterey Subbasin. In particular, the concepts of an Intermediate 180-Foot Aquitard and lack of a 180/400 Foot Aquitard do not apply outside of Fort Ord. Work completed by HWG demonstrates that the 180-Foot Aquifer is one vertically continuous aquifer and that the 180/400 Foot Aquitard is present (HWG, November 2017).	of the Marina Ord Area. The preponderance of evidence shows that this hydrogeologic conceptual model does exist in the northern portion of the Monterey Subbasin.
8. The GSP states that horizontal hydraulic conductivity in the DSA ranges from 0.14 to 120 feet/day (Section 4.2.1.2, Principal Aquifers, p.87). **HWG Comment:** It is important to distinguish the two major portions of what is referred to in the GSP as the DSA – coastal and perched/mounded. While the coastal DSA does have K values on the higher end of the cited range, perched/mounded portion of the DSA only has K values at the lower end of the cited range.	The distribution of measured hydraulic conductivities in the Dune Sand Aquifer are shown on Figure 4-20. These data are based upon specific capacity tests and aquifer testing at the identified locations and are consistent with the magnitude of hydraulic conductivity estimates presented for the Dune Sand Aquifer in the Monterey Subbasin GSP.
9. The GSP makes general statements on hydrogeologic interpretations of AEM data, including outside of the GSP Plan area (Section 4.2.1.2, Principal Aquifers, p. 88). **HWG Comment:** It is not clear why the GSP is speculating on aquifer conditions outside of the Monterey GSP Plan Area based solely on AEM data, and without consideration of geologic and well data. The GSP also provides no demonstration/evidence of how these conclusions were reached. The HWG has previously provided extensive documentation of erroneous hydrogeologic interpretations of the AEM data (HWG, November 2017, January 2018, August 2018, January 2019, March 2019, and April 2019). The HWG April 2019 document clearly demonstrates with field data that the hydrogeologic	The 2017 AEM Study[10] and 2019 AEM Study[11] for the Monterey Subbasin and surrounding area were performed by highly regarded professors of Geophysics and California Licensed Geophysicists including: • Dr. Rosemary Knight, Ph. D.: Professor of Geophysics at Stanford University, • Theodore H. Asch, CA GP#1038; California Licensed Professional Geophysicist with Aqua Geo Frameworks, LLC. • Jared D. Abraham CA GP#1089: a California Licensed Professional Geophysicist with Aqua Geo Frameworks, LLC. The 2017 AEM study has been peer reviewed[12] and has been validated against lithologic and water quality data within the Monterey Subbasin. Both studies have also been provided to California Department of Water

[10] Stanford/Aqua Geo Frameworks, 2018. *Interpretation of Hydrostratigraphy and Water Quality from AEM Data Collected in the Northern Salinas Valley, CA*, Ian Gottschalk, Rosemary Knight, Stanford University, Stanford, CA; Ted Asch, Jared Abraham, Jim Cannia, Aqua Geo Frameworks, Mitchell, NE, dated 15 March 2018.

[11] Aqua Geo Frameworks, 2019. *Final Report on the 2019 Airborne Electromagnetic Survey of Selected Areas Within the Marina Coast Water District*, dated 14 November 2019.

[12] Gottschalk, I., Knight, R., Asch, T., Abraham, J. and Cannia, J., 2020. Using an airborne electromagnetic method to map saltwater intrusion in the northern Salinas Valley, California. Geophysics, 85(4), pp.B119-B131. https://library.seg.org/doi/full/10.1190/geo2019-0272.1

HWG Comments	Responses
interpretations of aquitard gaps from the AEM study are invalid. Furthermore, as described above, MPWSP monitoring well borehole logs demonstrate that areas of uncertain aquitard continuity identified by MCWRA (who did not have MPWSP monitoring well borehole data available to them at the time of their study) near the northern Monterey Subbasin boundary are no longer uncertain and clearly have significant aquitard material present. Furthermore, review of water level and water quality data for the MPWSP clearly demonstrate the presence and continuity of the 180/400-Foot Aquitard in this area. The Monterey Subbasin GSP does not describe the applicability of the concept of a sea water wedge (i.e., where sea water intrusion occurs, less saline water often overlies more saline water in a given aquifer) to explain the expected presence of less saline water overlying more saline water in some areas of the vertically continuous 180-Foot Aquifer. The presence of less saline water in the upper portion of an aquifer does not demonstrate the aquifer is not sea water intruded. Furthermore, given the standard of 500 mg/L chloride applied by MCWRA for defining the area of seawater intrusion, the AEM data collected in the area are not capable of distinguishing between a chloride concentration below the standard (e.g., 200 mg/L) from a chloride concentration above the standard (e.g., 600 mg/L) given inherent uncertainties in AEM data interpretation and the complicating variable of lithologic influences on AEM data.	Resources (DWR) for review as part of a large new AEM Study that is being conducted by DWR across California. One of the primary authors of the 2017 AEM study, Dr. Ian Gottschalk, Ph. D., is one of the geophysicist working on DWR's study. It is noted that members of the HWG are not California Licensed Geophysicists with expertise in AEM collection and analysis. Geophysics is a highly specialized discipline and not within the established practice areas for licensed professional geologists. The revised draft of Chapter 4 of the Monterey GSP, dated 12 January 2021 does not address the continuity of the 180/400 Foot Aquitard within the 180/400 Foot Aquifer Subbasin as it is not relevant to the understanding and characterization of conditions within the Monterey Subbasin, which is the subject of the GSP. The mechanics of seawater intrusion and the "sea water intrusion wedge" is described in Monterey GSP Section 5.3.2. The GSP does not rely solely on AEM data to characterize seawater intrusion within the Monterey Subbasin. As shown on Monterey GSP Figure 5-24, characterization of water quality in the upper 180-foot Aquifer is based on hundreds of TDS measurements collected from wells screened in this aquifer. These data have been used to confirm AEM results, which are also presented on Figure 5-24.
10. The GSP states, "South of the City of Marina, in a portion of the former Fort Ord, the 180-Foot Aquifer is separated into an "upper" zone of sandy deposits with some gravel and a "lower" zone of gravel with sand and clay lenses; the two zones are separated by a thin clay layer (Ahtna Engineering, 2013). Data collected within the former Fort Ord show that significant head differences exist between the upper and lower ones of the 180-Foot Aquifer." (Section 4.2.1.2, Principal Aquifers, p. 91). HWG Comment: The HWG agrees that the area where this conceptual model applies is in a portion of former Fort Ord to the south of the City of Marina. However, the GSP implies this conceptual	Comparison of water levels shown on: • Figure 5-2: which presents groundwater level elevations in the Upper 180-Foot Aquifer, with • Figure 5-3: which presents groundwater level elevations in the Lower 180-Foot Aquifer and 400-Foot Aquifer Zone show that water levels in the Upper 180-Foot aquifer are approximately 5 to 10 feet higher than those in the Lower 180-Foot Aquifer and 400-foot aquifer north of Reservation Road in the Monterey Subbasin. Further, as shown on Figure 5-24 and consistent with other areas in the Marina Ord, TDS concentrations in groundwater within the Upper 180-Foot Aquifer are less than 1000 mg/L north of Reservation Road; whereas, TDS concentrations in the Lower 180-Foot Aquifer and 400 foot aquifer zones range between

HWG Comments	Responses
model (illustrated in Figure 4-13) applies throughout the GSP Plan Area, including north of Reservation Road, which is not correct as documented in work by HWG that is not referenced in this GSP (e.g., HWG, November 2017).	3,000 mg/L and >10,000 mg/L in this area. These data support the hydrogeologic conceptual model presented in the Monterey GSP.
11. The GSP discussion of the "Middle (180/400) Aquitard" suggests it is not present beneath the majority of the Marina-Ord Area, and implies this conceptual model applies throughout the Monterey Subbasin as illustrated by Figure 4-13 (Section 4.2.1.2, Principal Aquifers, p. 91). **HWG Comment:** As noted above with other aspects of the conceptual model presented in Figure 4-13, the concept that the 180/400 Foot Aquitard is not present in northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin is erroneous (see recent work by HWG not referenced in the GSP, as well as MCWD well logs). For example, HWG work demonstrates similar groundwater elevations in the upper and lower 180 Foot Aquifer (MW-6), and significantly different groundwater elevations and fluctuations in the 180 and 400 Foot Aquifers (multiple MPWSP monitoring wells).	See Response to Comment 7 above. Well MW-6 referenced by the HWG is not located in the Monterey Subbasin.
12. The GSP states, "The Lower 180-Foot Aquifer zone and the 400-Foot Aquifer in the vicinity of the City of Marina are functionally the same due to the missing Middle (180/400-Foot) Aquitard in this area." (Section 4.2.1.2, Principal Aquifers, p. 94). **HWG Comment:** As discussed above with other aspects of the Site Conceptual Model (Figure 4-13), this characterization does not apply to Northern Monterey Subbasin, contrary to what is stated/implied in the GSP.	See response to HWG Comment 7 above.
13. The GSP states, "Near the Monterey-Seaside subbasin boundary, a depression exists in the groundwater potentiometric surface of the 400-Foot Aquifer…These data suggest that a potential connection may exist between the 400-Foot Aquifer and the Deep Aquifer in this area." (Section 4.2.1.2, Principal Aquifers, p. 94.) **HWG Comment:** There is no geologic evidence provided in the GSP to support this statement. Preliminary review of geologic data (lithologic logs	The source of the depression is uncertain and will be identified as a data gap within the GSP. However, as discussed in Monterey GSP section 5.1.3.1 Two CASGEM wells in the southwestern portion of the Marina-Ord Area, MPWMD#FO-10 and MPWMD#FO-11, show consistent decreasing trends over the past 15-years. Additionally, groundwater elevations in these wells are significantly lower than those to the north near the City of Marina and to the south in the Seaside Subbasin. When water levels in these wells are plotted in conjunction with other 400-

HWG Comments	Responses
and Elogs) by HWG for MPWMD FO-10 and FO-11 indicate presence of sufficient thicknesses of clay layers to serve as aquitard layers between the 400-Foot and Deep Aquifers at this location.	Foot Aquifer wells in the Marina Ord Area, they indicate the presence of in a localized depression in the groundwater potentiometric surface of the 400-Foot Aquifer. However, there is no known extraction in the Monterey Subbasin in the vicinity of these wells and groundwater elevations observed in these wells are similar to those measured in the Deep Aquifers. These data suggest that (1) these wells are screened within sediments that connect directly to the Deep Aquifers; or (2) leakage is occurring from the 400-Foot Aquifer into the Deep Aquifers in the vicinity of these wells.
14. The GSP states, "As shown in Section 6 below, groundwater flow direction in the 400-Foot Aquifer is strongly influenced by groundwater pumping in the Salinas Valley Groundwater Basin, inland of the Monterey Subbasin." (Section 4.2.1.2, Principal Aquifers, p. 94) **HWG Comment:** A primary theme of this GSP here and elsewhere is that pumping in the 180/400 Foot Aquifer Subbasin is essentially solely responsible for seawater intrusion in the 180-Foot Aquifer and 400Foot Aquifer within Monterey Subbasin, and for depressed Deep Aquifer groundwater elevations in the within Monterey Subbasin. However, the history of groundwater development in the Monterey Subbasin demonstrates how groundwater production wells developed for MCWD and Fort Ord resulted in seawater intrusion in the 180-Foot Aquifer and 400-Foot Aquifers in Monterey Subbasin (for example, see quote below from Harding ESE, 2001). In addition, Deep Aquifer groundwater elevations were fluctuating around sea level prior to pumping of Deep Aquifer wells by MCWD that dropped Deep Aquifer groundwater elevations well below sea level. Thus, groundwater pumping from wells screened in the 180-Foot, 400-Foot, and Deep Aquifers within Monterey Subbasin have played a significant role in historical/current seawater intrusion and depressed groundwater elevations within Monterey Subbasin. Harding ESE (2001) states: "Seawater intrusion beneath the city of Marina was observed soon after installing several production wells in the 180-Foot Aquifer (MCWD-1, the first city well, was installed in 1956). Subsequent seawater intrusion into this area was closely related to ground water withdrawal by	Seawater intrusion within the Salinas Valley Groundwater Basin is the result of cumulative rates of groundwater extraction within the basin, which exceed freshwater recharge. However, the Monterey Subbasin water budget shows that inland cross boundary flows into the 180/400 Foot Aquifer Subbasin exceed total freshwater recharge to the Monterey Subbasin. Therefore, even if no groundwater was extracted within the Monterey Subbasin, the Monterey Subbasin would be in overdraft due to groundwater extraction from other portions of the Salinas Valley Basin. Therefore, the conclusion that groundwater extraction within other portions of the Salinas Valley Groundwater Basin (SVGB) are the primary cause of for seawater intrusion within the Monterey Subbasin is correct. Further, groundwater extracted within the Monterey subbasin does not exceed areal recharge to the subbasin. Additional information regarding the water budget for the Monterey Subbasin will be presented in Monterey GSP Chapter 6.

HWG Comments	Responses
the city of Marina and former Fort Ord. Deteriorating water quality forced the city of Marina to discontinue pumping most of its 180-Foot Aquifer wells by the late 1970's and install water-supply wells in the 400-foot (MCWD-8, -8a, and -9) and Deep Aquifers (MCWD-10, -11, and-12)."	
15. The GSP states with respect to the Deep Aquitard (otherwise known as 400 Foot/Deep Aquitard), "There is no analysis available for its spatial occurrence or geologic composition." (Section 4.2.1.2, Principal Aquifers, p. 95). **HWG Comment:** The GSP could have conducted the "missing" analysis of the aquitard for the Monterey Subbasin given that several MCWD production wells (e.g., MWCW 10, 11, 12) and other wells (e.g., USGS deep nested monitoring well, agricultural wells) have available lithologic and geophysical logs. Such an analysis would demonstrate the presence of a 200 to 300 foot thick clay layer (i.e., 400/Deep Aquitard) between the 400-Foot Aquifer and uppermost Deep Aquifer Zone. The lack of seawater intrusion in the Deep Aquifer, which has groundwater elevations on the order of 50 to 100 feet below sea level in the northern Monterey Subbasin area and a strong vertically downward gradient from the 400-Foot Aquifer, combined with high salinity in the 400-Foot Aquifer within and surrounding the northern Monterey Subbasin also shows the strong integrity of the aquitard between the 400-Foot Aquifer and Deep Aquifer. The large difference in water levels between the 400-Foot Aquifer and Deep Aquifers also provides evidence of a thick/tight aquitard separating these aquifer zones.	Boring logs from MCWD production wells MCWD-10, -11 and -12 and the USGS monitoring well informed cross sections on Figures 4-8, 4-9, and 4-11 Boring logs of MCWD-11 and MCWD-12 do show a 200 to 300 foot thick clay layer between the 400-Foot Aquifer and the Deep Aquifers. However, other wells within the subbasin (e.g. MCWD-10), show a series of thinner clay deposits between the 400 Foot Aquifer and the Deep Aquifer. The vertical gradients observed between the 400 Foot aquifer and Deep Aquifers, indicate that the series of clay deposits between these aquifer zones create substantial barriers to vertical flow.
16. The GSP describes the Reliz Fault as displaced the Monterey Formation, which is the base of the Deep Aquifer, shifted downward on the northeast side by 1,000 feet. It then states the fault does not appear to impede groundwater flow within the Dune Sand Aquifer, 180-Foot Aquifer, or 400-Foot Aquifers (Section 4.2.1.3, Structural Restrictions to Flow, p. 98). **HWG Comment:** The GSP does not comment on the possibility of the Reliz Fault altering groundwater flow within the Deep Aquifer.	There is insufficient data to evaluate the extent to which the Reliz Fault may alter flow within the Deep Aquifers. However, available water level data suggests that groundwater flows readily between the Monterey and 180/400 Foot aquifer Subbasin within the Deep Aquifer zones near the Reliz fault as shown on Figures 5-4 and 5-8. Therefore, if it does alter flow, the impacts appear to be localized.

HWG Comments	Responses
17. This section of the GSP begins, “This Section presents a general discussion of the natural fresh groundwater quality in the Marina-Ord Area, focusing on general geochemistry (Section 4.2.1.4, General Water Quality, p. 98). **HWG Comment:** Given the significance of historical and ongoing seawater intrusion in the Dune Sand Aquifer, 180-Foot Aquifer, and 400-Foot Aquifer in the Marina-Ord Area, it is unclear why this section would only describe the fresh water within the Marina-Ord Area.	As stated in the 2nd sentence of this Section 4.2.1.4, “The distribution and concentrations of specific constituents of concern, including seawater intrusion, are discussed in Chapter 5. Consistent with SGMA guidance, seawater intrusion is assessed independently from other water quality parameters within the GSP, as it is one of the six “Undesirable Results” designated under SGMA.
18. With regard to the Dune Sand Aquifer, the GSP states, “Groundwater in this aquifer is primarily fresh; minimal seawater intrusion has occurred in this aquifer (Section 4.2.1.4, General Water Quality, p. 98). **HWG Comment:** The coastal Dune Sand Aquifer is intruded by seawater, as demonstrated by monitoring wells at the MCWD office on Reservation Road (Staal, Gardner & Dunne, 1991 and 1992; Fugro West, 1996, 2001) and in the vicinity of the CEMEX site (HWG, November 2017).	Current groundwater data from over 20 monitoring wells and AEM data have been used to evaluate the extent of seawater intrusion within the Dune Sand Aquifer in 2017 (See Figure 5-24) within the Monterey Subbasin. Historical data collected from over 25 years ago has not been included in the GSP, nor is data collected from the CEMEX site which is located in the 180/400 Foot Aquifer Subbasin.
19. The GSP states, “The Dune Sand Aquifer contributes recharge to the 180-Foot Aquifer…” (Section 4.2.1.4, General Water Quality, p. 98). **HWG Comment:** It should be noted that this recharge from the Dune Sand Aquifer to the 180-Foot Aquifer is minimal (likely on the order of a few hundred acre-feet per year). This recharge has not stopped seawater intrusion from occurring in this area.	Areal recharge is the primary source of freshwater recharge to the Monterey Subbasin. Given that the Dune Sand aquifer overlies approximately 1/2 of the Marina Ord Area, Recharge to the Dune Sand Aquifer is one of the most significant sources of freshwater recharge to this portion of the Monterey Subbasin. As shown on Monterey GSP Figure 5-24 the fresh water exists in both the Dune Sand Aquifer and the Upper-180 Foot aquifer, which is recharged by the Dune Sand Aquifer across the Marina Ord Area. Further, although seawater intrusion exists within the Lower 180- Foot Aquifer and 400-Foot Aquifer in the northern portion of the Marina Ord Area, the southern portion of the Monterey Subbasin has not been seawater intruded (see Monterey GSP Figure 5-28), and is supported by recharge from the Dune Sand Aquifer. These facts support the conclusions presented in the Monterey GSP. Groundwater elevation information and estimate specific yield indicates that approximately 80,000 AF to 160,000 AF of groundwater exist within the Dune Sand and upper 180-foot aquifer (Section 8.8.3.1). Water quality and AEM data indicate that this groundwater is fresh.
Chapter 5 – Groundwater Conditions	

HWG Comments	Responses
1. The GSP notes data sources used in the GSP, which includes documents/data for Monterey Peninsula Landfill (Section 5.1.1, Data Sources, p. 6). **HWG Comment:** We note that Monterey Peninsula Landfill (MPL) is not located within Monterey Subbasin. In addition, if data from Monterey Peninsula Landfill are being used, why are data from MPWSP monitoring network not being used. Notably, later in Chapter 5, the GSP uses AEM data outside of Monterey Subbasin and within the area of MPWSP monitoring network data, yet there is no use of MPWSP data that contradicts the hydrogeologic interpretation of AEM data provided in the GSP.	The GSP incorporates information developed as part of the Monterey Peninsula Supply Project (MPWSP), to the extent that it is relevant to the GSP. However, the 8 well clusters completed as part of the MPWSP are located in the immediate vicinity of the MPWSP and are all located within the 180/400 Foot Aquifer Subbasin. None of these wells are located within the Monterey Subbasin, nor is the MPWSP the focus of this GSP.
2. The GSP states that the Dune Sand Aquifer is a Principal Aquifer and that the 180-Foot Aquifer contains two distinct layers, known as the upper- and lower- 180-Foot Aquifer (Section 5.1.2.1, MarinaOrd Area, p.7). **HWG Comment:** The Dune Sand Aquifer should not be designated as a Principal Aquifer, and is in conflict with the 180/400 Foot Aquifer Subbasin GSP in this regard. Furthermore, the splitting of the 180-Foot Aquifer into two distinct aquifers only applies in the Fort Ord area, and does not apply in northern Monterey Subbasin (HWG, November 2017). While the entire thickness of the 180-Foot Aquifer is intruded by seawater near the coast and for a significant distance inland, the presence of less saline water within the upper portion of the 180-Foot Aquifer further inland is merely a function of the nature of seawater intrusion wedges, and not a function of the presence of an intermediate aquitard within the 180-Foot Aquifer in northern Monterey Subbasin.	See response to HWG Chapter 4 Comment 5.
3. The GSP describes groundwater flow conditions in the 180-Foot Aquifer, and states, "…inflow from the Dune Sand Aquifer protects the upper 180-Foot Aquifer from seawater intrusion." (Section 5.1.2.1, Marina-Ord Area, p.8). **HWG Comment:** Any groundwater flow that may occur from the Perched/Mounded portion of the inland Dune Sand Aquifer to the underlying 180-Foot Aquifer has historically not prevented seawater	There are hundreds of wells located in the upper 180-foot aquifer that show that TDS concentrations are below 1,000 mg/L. See Monterey GSP Figure 5-24.

HWG Comments	Responses
intrusion from occurring within the 180-Foot Aquifer, which has been and remains heavily intruded with seawater. Any claims to the contrary, such as in this referenced statement from the Monterey Subbasin GSP, are incorrect. As noted above, there are not geologically distinct Upper and Lower 180 Foot Aquifers in northern Monterey Subbasin. The amount of recharge from the Dune Sand Aquifer to the 180-Foot Aquifer is small, as can easily be demonstrated by calculation of the amount of precipitation recharge in the Dune Sand Aquifer within the area west of the groundwater divide that has potential to recharge the 180-Foot Aquifer (e.g., on the order of a few hundred AFY, before subtracting Ford Ord remedial pumping). Furthermore, in order to dilute incoming seawater to a fresh water concentration, there would need to be over 30 times more fresh water than seawater in the mixing zone to create a net fresh water condition. Thus, a few hundred AFY of fresh water can effectively only dilute about 10 to 20 AFY of incoming seawater.	
4. The GSP states, "…the lower 180-Foot Aquifer is hydraulically connected to the 400-Foot Aquifer in the Marina-Ord Area due to the discontinuous nature of the 180/400-Foot Aquitard within this region…As such, groundwater elevation and gradients in the lower 180-Foot Aquifer are similar to those in the 400-Foot Aquifer in the Marina Ord Area of the Subbasin…" (Section 5.1.2.1, Marina-Ord Area, p.8). **HWG Comment:** This characterization of the discontinuous nature of the 180-400 Aquitard is not applicable to the northern portion of the Monterey Subbasin. Groundwater levels in the 180-Foot Aquifer and 400-Foot Aquifer are clearly different and distinct in the northern half of Monterey Subbasin and in the adjacent 180/400-Foot Aquifer Subbasin (HWG, November 2017). The Monterey Subbasin GSP does not demonstrate the similarity or difference in groundwater elevations to justify its characterization.	See response to HWG Chapter 4 Comment 7.
5. Figures 5-1 and 5-5 show the western extent of the FO-SVA north of Monterey Subbasin as extending to MPWSP MW-3.	These figures will be modified to remove the estimate extent of the FO-SVA outside of the Monterey Subbasin, as this is information is not relevant to the Monterey GSP.

HWG Comments	Responses
HWG Comment: The extent of FO-SVA shown on the maps is outdated and also does not incorporate more recent data and analyses based on the MPWSP borehole/well data. We also note that groundwater elevation figures for all units except the Dune Sand Aquifer extend northward across the Monterey Subbasin/180-400 Foot Aquifer Subbasin boundary, even though many Dune Sand Aquifer well locations are available and shown on the figures for the MPWSP and MPL monitoring networks. In addition, there are several monitoring wells located at the MCWD District office headquarters and treatment plant on Reservation Road near the coast (Staal, Gardner & Dunne, 1991 and 1992; Fugro West, 1996 and 2001).	
6. In describing groundwater elevations in the 400-Foot Aquifer the GSP states, "A local groundwater depression exists just north of the Monterey-Seaside Subbasin boundary where a potential connection between the 400-Foot Aquifer and the Deep Aquifers may be located ." (Section 5.1.2.1, Marina-Ord Area, p.8). **HWG Comment:** The GSP provides no geologic evidence for a potential connection at this location between the two aquifers. The GSP only cites to HLA (2001) for cross-sections in this area, but other geologic cross-sections are available to consider from previous reports (e.g., HWG, 2017; Yates et.al., 2005). The location of this depression, which is more centrally located within Monterey Subbasin than described in the GSP text, is only about 1.5 miles south of MCWD Deep wells where a thick (i.e., 200 to 300 feet) aquitard exists between the 400 Foot Aquifer and Deep Aquifer.	See response to HWG Chapter 4 Comment 13.
7. GSP Figures 5-1 and 5-5 (Groundwater Level Contours in the Dune Sand Aquifer – Fall 2017 and Spring 2018) show locations of MPWSP and MPL wells, but do not use the data to prepare groundwater level contours. **HWG Comment:** It is not clear why the GSP maps would show these MPWSP/MPL well locations but not use the data. We also note that geologic and borehole geophysical data from these wells are not used in developing geologic cross-sections or to develop an understanding of the geologic conditions	Groundwater levels for the Dune Sand Aquifer have not been extended into the 180/400 Foot Aquifer Subbasin, as they do not affect the conclusions or projects included in this GSP.

HWG Comments	Responses
for the HCM. This is particularly noteworthy in that the GSP Chapter 5 later uses hydrogeologic interpretations from the AEM data in lieu of actual borehole/well data to derive different conclusions regarding the HCM that are not supported by borehole/well data.	
8. GSP Figures 5-2 and 5-5 (Groundwater Level Contours in the 180-Foot Aquifer – Fall 2017 and Spring 2018) show locations of only three of the MPWSP wells (MW-6, MW-8, and MW-9), and do not use data from MW-8 and MW-9. **HWG Comment:** It is not clear why the GSP maps only show selected MPWSP well locations and do not use most of the data from the selected wells that are shown on the maps. We also note that geologic and borehole geophysical data from these wells are not used in developing geologic cross-sections or in developing an understanding of the geologic conditions underlying the HCM. This is particularly noteworthy in that the GSP Chapter 5 later uses hydrogeologic interpretations from the AEM data in lieu of actual borehole/well data to derive different conclusions regarding the HCM that are not supported by borehole/well data. We also note that groundwater is indicated to flow inland from the ocean to a pumping center in the north central portion of Monterey Subbasin.	The Monterey GSP focuses on wells located in the Monterey Subbasin and wells located immediately adjacent to the subbasin within the 180/400 Foot Aquifer subbasin to provide continuity with water levels in that subbasin.
9. Figures 5-3 and 5-7 (Groundwater level Contours in the 400-Foot Aquifer – Fall 2017 and Spring 2018) show a +10 feet MSL contour as the shoreline in Marina Subbasin. **HWG Comment:** There is no well control to support this +10 feet MSL contour line, or even the zero contour line. We note that groundwater elevations in the 400-Foot Aquifer for MPWSP MW-3 (very close to the shoreline) ranged from 0 to -15 feet NAVD88 during this time period. We also note that groundwater is indicated to flow inland from the ocean to a depressed area in the south central portion of Monterey Subbasin. The Fall 2017 groundwater levels show that the pumping depression in the southern central area of Monterey Subbasin contributes to a broader depression that extends to the 180/400 Foot Aquifer Subbasin. Spring 2018 groundwater levels appear to indicate	The revised draft of Chapter 5 of the Monterey GSP does not show a +10 feet contour on Figures 5-3 and 5-7.

HWG Comments	Responses
occurrence of a temporal groundwater divide around the MCWD well field.	
10. The GSP states, "…water levels in the Dune Sand Aquifer increase and decrease during extended wet and dry periods." This statement is apparently in reference to Figure 5-11: Representative Groundwater Elevation Hydrographs in the Dune Sand Aquifer (Section 5.1.3.1, Long-Term Groundwater Elevation Trends, Marina-Ord Area, p. 21). **HWG Comment:** The seven hydrographs shown in Figure 5-11 do not appear to respond to wet and dry periods. The only short-term response observed is around the year 2000 in the hydrograph for MW-OU2- 05-A. This apparent stability of groundwater levels in the Perched/Mounded portion of the Dune Sand Aquifer is quite unlike the seasonal fluctuations that occur in response to pumping in the underlying aquifers, and further confirms that the DSA is undeveloped and essentially undevelopable as a water supply and therefore not a Principal Aquifer.	See response to HWG Chapter 4 Comment 2.
11. The GSP states, "Groundwater elevations in the Lower 180-Foot Aquifer are generally equivalent to those observed in the 400-Foot Aquifer…" (Section 5.1.3.1, Long-Term Groundwater elevation Trends, 180-Foot Aquifer, Lower 180-Foot Aquifer, p. 21). **HWG Comment:** The GSP provides no evidence that groundwater elevations in the Lower 180-Foot Aquifer are equivalent to those in the 400-Foot Aquifer. In addition, no geologic evidence is provided that defines distinct Upper and Lower 180-Foot Aquifers in terms of a continuous intermediate aquifer throughout the Monterey Subbasin. MPWSP monitoring well MW-6 is a nested well cluster with separate wells in the upper and lower 180-Foot Aquifer and shows essentially identical groundwater elevations and fluctuations – it is located along Blanco Road on the border of the Monterey Subbasin with the 180/400-Foot Aquifer Subbasin.	As shown in Figure 5-13, the two multi-completion wells (MP-BW-37 and MP-BW-41) screened from 286 ft bgs to 460 ft bgs showed identical water levels, suggesting that the groundwater elevations in the Lower 180-Foot Aquifer are equivalent to those in the 400-Foot Aquifer.
12. The GSP states that groundwater elevation data for MPWMD#FO-10 and MPWMD#FO-11	See Response to HWG Chapter 4 Comment 13.

HWG Comments	Responses
suggest, "…(1) these wells are screened within sediments that connect directly to the Deep Aquifers; or (2) leakage is occurring from the 400-Foot Aquifer into the Deep Aquifers in the vicinity of these wells." (Long-Term Groundwater Elevation Trends, 400-Foot Aquifer, p. 22). **HWG Comment:** Insufficient evidence is provided to make the stated conclusions; for example, no geologic evidence is provided to support these claims. In addition, more groundwater elevation data are needed to evaluate the gradient and flow direction in this portion of the aquifer. Preliminary review of geologic data (lithologic logs and Elogs) by HWG for MPWMD FO-10 and FO-11 indicate presence of sufficient thicknesses of clay layers to serve as aquitard layers between the 400-Foot and Deep Aquifers at this location.	
13. GSP Figure 5-15 shows groundwater hydrographs for Deep Aquifer wells near the Monterey Subbasin and 180/400-Foot Aquifer Subbasin boundary. Figure 5-16 shows Deep Aquifer groundwater pumping over time. In reference to the adjacent 180/400-Foot Aquifer Subbasin, the GSP states that, "…groundwater elevations in wells located near Cooper Road and Blanco Road have declined more than 5 ft/year over the past 15 years." **HWG Comment:** We note that the three wells in the 180/400-Foot Aquifer Subbasin have data through about 2020 and generally show fluctuating but overall stable groundwater elevations from about 2015 to 2020. Several of the MCWD wells within the Monterey Subbasin shown in the figure are lacking data from about 2017 to 2020, but the overall trend from available data appears to be declining groundwater elevations within Monterey Subbasin from 2015 to 2020. We note that Figure 5-16 shows significant increases in both agricultural and urban pumping from the Deep Aquifer after 2013, with urban pumping comprising approximately half of the total Deep Aquifer pumping over that time period. Figure 5-16 shows a doubling of urban pumping between 2013 and 2018, but no discussion/explanation of the sharp jump in urban pumping is provided in the text. Overall, the characterization of recent Deep Aquifer	Figure 5-15 shows significant declining groundwater trends in the deep aquifers in the Monterey and 180/400-Foot Aquifer Subbasins. A comparison of MCWD pumping in the deep aquifer has been added to Figure 5-16, which has been stable since the 1990s.

HWG Comments	Responses
groundwater elevation trends between the two subbasins in the text appears to be inaccurate based on review of the figures.	
14. The GSP states, "These downward vertical gradients are caused by areal surface recharge, groundwater extraction from deeper aquifers, and laterally extensive aquitards, which exist in the Marina-Ord Area." (Section 5.1.4, Vertical Hydraulic Groundwater Gradients, pp. 31-32). **HWG Comment:** We note that the GSP references the presence of laterally extensive aquitards separating Principal Aquifers throughout Monterey Subbasin, a statement that we agree with, and yet the conceptual model described in GSP Chapters 4 and 5 provides for essentially no aquitard between the 180-Foot and 400-Foot Aquifers and a big hole in the thick aquitard between the 400-Foot Aquifer and Deep Aquifers.	The conceptual model presented in Chapters 4 and 5 does not imply that extensive aquitards do not exist in the Marina Ord Area. However, the data does indicate that the aquitard that is observed between the 180- and 400-foot aquifers in the 180/400 Foot Subbasin is not as prevalent in the Marina Ord Area. Further, the conceptual site model does state that a series of aquitards exist between the 400 Foot Aquifer and the Deep Aquifers, which significantly reduce vertical groundwater migration. The available data do not suggest that it is one thick continuous aquitard across the Marina Ord area.
15. The GSP states that in the central Marina-Ord Area the groundwater elevations in the upper 180-Foot Aquifer are 70 feet lower than in the Dune Sand Aquifer (Section 5.1.4, Vertical Hydraulic Groundwater Gradients, p. 32). **HWG Comment:** This 70 foot difference in groundwater elevation almost certainly reflects the presence of perched aquifer conditions in the Dune Sand Aquifer at this location, which is why the HWG refers to the portion of the so-called Dune Sand Aquifer overlying the FO-SVA as the Perched/Mounded Aquifer. This observation also begs the question of why the Dune Sand Aquifer is being classified as a Principal Aquifer in this GSP, when much of it is a thinly saturated perched aquifer.	See response to HWG Chapter 4 Comment 2.
16. The GSP states, "Within the Monterey Subbasin, seawater intrusion has been documented in the northern portion of the lower 180-Foot and 400-Foot Aquifers." (Section 5.3, Seawater Intrusion, p. 36). **HWG Comment:** As discussed other HWG comments in this letter, the designation of a geologically distinct lower 180-Foot Aquifer does not apply in the northern portion of the Monterey Subbasin. The entire thickness of the 180-Foot Aquifer is intruded at the coast and for some	See responses to: HWG Chapter 4 comments 5 and 7, and HWG Chapter 5 comment 3

HWG Comments	Responses
distance inland, with a seawater wedge having formed further inland (i.e., less saline water overlying more saline water due to density differences).	
17. The GSP describes data sources used in their analysis of seawater intrusion for the GSP, which include two airborne electromagnetic (AEM) surveys (Section 5.3.1, Seawater Intrusion, Data Sources, p. 36). **HWG Comment:** We note that the GSP utilizes an AEM profile entirely within the 180/400-Foot Aquifer Subbasin that passes through/near several MPWSP boreholes/wells, yet the GSP does not use the readily available MPWSP borehole/well data in its analysis. Furthermore, the HWG has conclusively demonstrated in previous documents (e.g., HWG, April 2019) that hydrogeologic interpretations derived from AEM data are flawed and inconsistent with borehole/well data.	Figures 5-26 and Figures 5-27 provide insights regarding the vertical profile of seawater intrusion within the Monterey Subbasin. These profiles include AEM Data, logged borehole data, and water quality data from each of the borings identified. As such, the reader can see how all of these sources of data correlate. The premise that that water quality data from well MW-7 is inconsistent with AEM data, is not correct. Detailed review of Cross Section A-A, which presents both AEM data and water quality data from well M-7, shows that TDS concentrations detected in groundwater samples collected from each well screen, reflect an average of the AEM profile that intersects the screen interval. As stated in Monterey Section 5.3.3: Cross-Section A-A', which is located immediately north of the Monterey Subbasin has been included in the GSP, to provide insight regarding the vertical delineation of seawater intrusion within the coastal areas of the Monterey Subbasin. AEM data along Cross Section B-B, which is located in the Subbasin, is sporadic due to the absence of AEM data in urban areas where high density of utilities interferes with AEM data collection.
18. The GSP devotes several pages and two figures (5-26 and 5-27) to describing AEM surveys, primarily a profile entirely outside of the Monterey Subbasin (Section 5.3.1.2, Geophysical Data, pp. 36-38, 41-42, and 45-46). **HWG Comment:** It is not clear why the GSP relies so heavily on AEM data (primarily outside the Monterey Subbasin) in its discussion of seawater intrusion (and disregards borehole/well data for the same area) – especially given the flaws in the hydrogeologic and groundwater quality interpretations made using AEM data previously described in multiple HWG documents (e.g., January, March, April 2019). The hydrostratigraphy shown on the AEM profiles (Figures 5-26 and 5-27) is incorrect; particularly with regard to its depiction of aquitards (i.e., the presence of a continuous intermediate aquitard within the 180-Foot Aquifer and absence of a 180/400 Aquitard). In essence, the GSP is inappropriately trying to apply the Fort Ord	See responses to: HWG Chapter 5 Comment 17 above.

HWG Comments	Responses
hydrogeologic conceptual model (developed for a limited area south of Reservation Road) throughout the northern Monterey Subbasin and into the adjacent 180/400 Foot Aquifer Subbasin. Field borehole/well data demonstrate that application of the Fort Ord HCM to northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin is incorrect. There is no evidence/basis to support the stratigraphic interpretations in Figures 5-26 and 5-27 related to the presence (or absence) of aquitards between various aquifers. We note that there are no control points for the majority of the cross-section in Figure 5-26, yet the figure implies an abundance of fresh water. Field water quality data from MW-7M do not match that indicated on the profile. The two profiles are inconsistent; where control points exist with a TDS color coded legend the profiles are not shaded accordingly; however, where no control points exist to validate AEM water quality the profiles are shaded.	
19. In describing the purpose of the AEM surveys, the GSP states, "The studies' goal was to evaluate the understanding of the hydrostratigraphy in the study area and to interpret that distribution of groundwater quality indicated by available well data." (Section 5.3.1.2, Geophysical Data, p. 37). **HWG Comment:** While this statement references "available well data", it does not actually cite or use available well data. Rather, the GSP interpretations of hydrostratigraphy and seawater intrusion in this section are based primarily on interpretations of AEM data that are at odds with well data (see various HWG documents such as January 2019, March 2019, and April 2019).	Well data are presented on all cross-sections and areal maps that include AEM Data within the GSP. The AEM data aid in the understanding the extent of seawater intrusion and hydrostratigraphy, however, all conclusions presented in the GSP are supported by actual well data.
20. The GSP describes how AEM data (i.e. electrical resistivity) are dependent on, "…the amount of clay, the amount of water, and/or the salinity of the water…" (Section 5.3.1.2, Geophysical Data, p. 37). **HWG Comment:** While we agree with this statement, these facts also point out the high level of uncertainty associated with interpretation of AEM	See response to HWG Chapter 5 Comment 19.

HWG Comments	Responses
data in this coastal seawater intruded setting where multiple variables are impacting recorded AEM (resistivity) values. This allows for multiple non-unique interpretations of AEM data to be made in such settings, which creates more uncertainty in those hydrostratigraphic and groundwater quality interpretations. The GSP itself acknowledges that water quality interpretation is "difficult to discern" for a wide range of AEM resistivity values. The GSP does not acknowledge that geochemical interpretation of AEM resistivity values even outside of the cited large range are still subject to uncertainties related to variation in lithologic/saturation conditions.	
21. The GSP states, "The AEM surveys have found that high salinity groundwater as a result of seawater intrusion exists within the lower 180-Foot Aquifer and 400-Foot Aquifers of the Monterey Subbasin. This volume of high salinity groundwater is overlain by fresh groundwater in the Dune Sand and upper 180-Foot Aquifers. The results of the AEM study are consistent with water quality data collected within the Subbasin (EKI, 2019)." (Section 5.3.1.2, Geophysical Data, p. 38). **HWG Comment:** Both the AEM data and borehole/well data demonstrate that the coastal Dune Sand Aquifer and essentially the entire thickness of the 180-Foot Aquifer are seawater intruded from the ocean shoreline to approximately one mile inland. At that point, the coastal Dune Sand Aquifer begins to transition to the Perched/Mounded Aquifer that overlies of FO-SVA that is generally not seawater intruded because it is an elevated thinly saturated perched aquifer further inland, and the fully seawater intruded area of the 180-Foot Aquifer transitions to a seawater intrusion wedge with less saline water overlying more saline water due to density differences. While the results of the AEM survey may be consistent with the primarily Perched/Mounded Aquifer groundwater quality data cited in EKI (2019), the AEM survey based hydrostratigraphic and groundwater quality interpretations are inconsistent with the groundwater quality data collected for the MPWSP	See responses to HWG Chapter 4 comments 5 and 7, and HWG Chapter 5 Comments 3 and 19.

HWG Comments	Responses
(e.g., HWG, April 2019) and key MCWD and Seaside Basin wells.	
22. The GSP presents an analysis (Figure 5-23) that demonstrates the definition of 500 mg/L chloride as the threshold for defining seawater intrusion is equivalent to a TDS of 1,000 mg/L. The GSP also cites the State of California upper Secondary Maximum Contaminant Level of 1,000 mg/L for TDS (Section 5.3.2, Defining Seawater Intrusion, p. 40). **HWG Comment:** We concur with the use of 500 mg/L chloride (although a good argument can be made for use of 250 mg/L chloride as a better indicator) and 1,000 mg/L TDS as an appropriate standards/thresholds for drinking water and seawater intrusion. We note that the AEM studies (study authors and study proponents) continue to argue for a drinking water and seawater intrusion threshold of 3,000 mg/L TDS, but this is at odds with GSP stated seawater intrusion and drinking water standards/thresholds of 500 mg/L and 1,000 mg/L TDS. Furthermore, due to the significant uncertainties in AEM groundwater quality interpretations, the AEM studies primarily attempt to differentiate groundwater above and below 3,000 mg/L TDS. The use of AEM data with a lower cutoff value (e.g., 1,000 mg/L TDS) results in even greater uncertainty in interpreted results than are achieved using the already uncertain AEM interpretations based on a cutoff of 3,000 mg/L TDS. We note that the GSP adopts a double standard by saying seawater intrusion has occurred when TDS exceeds 1,000 mg/L or chloride exceeds 500 mg/L in the Deep Aquifer, yet concentrations of 3,000 mg/L TDS and over 1,000 mg/L chloride represent low-TDS groundwater that is considered a source of drinking water supply in the AEM studies cited in the GSP.	The GSP selects 500 mg/L chloride to estimate the extent of seawater intrusion within the Subbasin. However, as discussed in Section 3.2.2.6, beneficial use criteria for the Subbasin are established pursuant to Water Quality Control Plan for the Central Coastal Basin, (Basin Plan) (State Water Resources Control Board (SWRCB), 2017). The Basin plan lists beneficial users, describes the water quality which must be maintained to allow those uses, provides an implementation plan, details SWRCB and Central Coast Regional Water Quality Control Board plans and policies to protect water quality and a statewide surveillance and monitoring program, as well as regional surveillance and monitoring programs. The SWRCB's Sources of Drinking Water Policy, adopted in Resolution No. 88-63 and incorporated in its entirety in the Basin Plan, provides that water with TDS less than or equal to 3,000 mg/L is considered suitable or potentially suitable for drinking water beneficial uses. As discussed in the Response to HWG Chapter 5 Comment 19: Well data are presented on all cross-sections and areal maps that include AEM Data within the GSP. The AEM data aid in the understanding the extent of seawater intrusion and hydrostratigraphy, however, all conclusions presented in the GSP are supported by actual well data.
23. In reference to the AEM profiles shown in Figures 5-26 and 5-27, the GSP states, "TDS and AEM data shown on these cross-sections confirm that seawater intrusion in the Monterey Subbasin primarily exists in the lower 180-Foot Aquifer and 400-Foot Aquifer, whereas groundwater in the Dune Sand and upper 180-Foot Aquifers remains	See Response to HWG Chapter 5 Comment 17.

HWG Comments	Responses
fresh." (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, p. 41). **HWG Comment:** While the statement refers to Monterey Subbasin, it should be noted that the Figure 526 is located entirely outside (north of) Monterey Subbasin, and Figure 5-27 contains very little data for the AEM profile within Monterey Subbasin. Furthermore, we have previously commented (in this letter and previous documents) on the flaws in the hydrostratigraphic and water quality interpretations shown on these AEM profiles (e.g., HWG, April 2019). Actual borehole/well data show the coastal Dune Sand Aquifer and entire thickness of the 180-Foot Aquifer are heavily intruded with seawater at the coast and for a significant distance inland. We recommend that AEM data only be used where results can be clearly validated with actual lithologic and water quality data. By not using this approach, the groundwater conditions are being misrepresented.	
24. In reference to the 180-Foot and 400-Foot Aquifers, the GSP states, "It appears that seawater intrusion in these two aquifers forms a unified intrusion wedge, due to the discontinuity of the 180/400 Foot Aquitard near the coast." (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, p. 41). **HWG Comment:** The HWG has previously demonstrated the flaws and inaccuracies in the hydrostratigraphic/water quality interpretations from AEM data inherent in this statement (i.e., absence of 180/400 Aquitard) (see HWG, April 2019).	See Response to HWG Chapter 5 Comment 17.
25. The GSP states, "Based on available TDS and AEM data, Figure 5-28 depicts the estimated extent of seawater intrusion within the Monterey Subbasin." (Section 5.3.3 Seawater Intrusion Maps and CrossSections, p. 41). **HWG Comment:** The area covered by Figure 5-28 does not include the AEM profile shown in Figure 5-26 and the AEM profile in Figure 5-27 provides very little data for the mapped area in Figure 5-28. Therefore, Figure 5-28 presumably is based essentially exclusively on TDS data. Furthermore,	See Response to HWG Chapter 5 Comment 17.

HWG Comments	Responses
the area covered by Figure 5-28 has separate 180-Foot and 400-Foot Aquifers separated by an aquitard, so one map is mixing data from different aquifers and should be revised to be two separate figures as is done by the MCWRA.	
26. The GSP states, "…the 180-Foot Aquifer in the Subbasin is divided by an intermediate aquitard into an upper zone and a lower zone. There is no observed seawater intrusion in the upper portion of the 180-Foot Aquifer." (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, pp. 41-42). **HWG Comment:** As discussed previously in this letter, the area covered by Figure 5-28 does not have a continuous intermediate aquitard in the 180-Foot Aquifer, does have a 180/400-Foot Aquitard, and seawater intrusion is present in a significant zone along (and inland of) the ocean throughout the entire thickness of the 180-Foot Aquifer (see HWG, 2017; Staal, Gardner & Dunne, 1992; Fugro West 1996 and 2001).	See responses to HWG Chapter 4 comments 5 and 7, and HWG Chapter 5 Comments 3 and 19.
27. In reference to Figure 5-28, the GSP states, "The figure shows that depressed groundwater elevations in the 180/400 Foot Aquifer Subbasin are creating inland groundwater gradients that are contributing to seawater intrusion within the Monterey Subbasin." (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, pp. 41-42). **HWG Comment:** It should be noted that there are also depressed groundwater elevations from groundwater pumping within the Monterey Subbasin that are contributing to inland groundwater gradients that are contributing to seawater intrusion within the Monterey Subbasin. In fact, the groundwater elevation contour map provided in Figure 5-28 indicates flow lines from the ocean end in a groundwater depression within the Monterey Subbasin. Furthermore, much greater historical pumping from Fort Ord and MCWD wells within the Monterey Subbasin created seawater intrusion within the Monterey Subbasin. Once seawater intrusion occurs, it requires many decades of maintaining seaward gradients to flush saline water back out of the aquifers.	See Response to HWG Chapter 4 Comment 14.

HWG Comments	Responses
28. GSP Figure 5-24 purports to show TDS concentrations and the extent of seawater intrusion in Monterey Subbasin (Section 5.3.3 Seawater Intrusion Maps and Cross-Sections, p. 43). **HWG Comment:** The dark blue zone in the Dune Sand Aquifer map extending approximately 0.5 miles inland from the shoreline suggests presence of fresh water coastal Dune Sand Aquifer, which is attributed to the 2018 AEM Survey report according to the map legend. The light blue zone that presumably attempts to define TDS concentrations below 1,000 mg/L includes a lobe that extends west of the FO-SVA extent that is not supported by any well data. On the contrary, available well data from the MCWD office site on Reservation Road for the Dune Sand Aquifer shows significant seawater intrusion has occurred in the area the AEM Survey report shown to be fresh water in the Dune Sand Aquifer along the coast (Staal, Gardner & Dunne, 1991 and 1992; Fugro West, 1996a and 1996b; Fugro West, 2001).	See Response to HWG Chapter 4 Comment 18.
29. The GSP states, "…seawater continues to flow across the area that is intruded towards the 180/400 Foot Aquifer Subbasin, while there is minimal migration of seawater intrusion to inland areas of the Monterey Subbasin. (Section 5.3.4, Historical Progression of Seawater Intrusion, p. 48.) **HWG Comment:** While the title of this GSP section refers to "Historical Progression of Seawater Intrusion", it fails to actually discuss the historical progress of seawater intrusion within Monterey Subbasin. As indicated in seawater intrusion maps prepared by MCWRA (Appendix 5B), a significant lobe of seawater intrusion into the 180-Foot Aquifer and 400-Foot Aquifer solely within Monterey Subbasin occurred south of Reservation Road in the 1970's and 1980's. This initial seawater intrusion into Monterey Subbasin occurred as a result of groundwater pumping from MCWD and Fort Ord wells screened in the 180-Foot Aquifer and 400-Foot Aquifer production zones, which were sequentially abandoned and moved inland and/or deeper as seawater intrusion moved inland in response to pumping of MCWD and Fort Ord production wells (Harding ESE, 2001). Most of the saline water that	See Response to HWG Chapter 4 Comment 14.

HWG Comments	Responses
was induced to flow into Monterey Subbasin in the 1970s and 1980s still resides in Monterey Subbasin aquifers, and remains part of the overall area of seawater intrusion that exists today.	
30. Figure 5-29 of the GSP (Total Dissolved Solid Concentration Trends in the Lower 180-Foot, 400-Foot Aquifer) shows historical and recent TDS concentrations in various wells, including MCWD Wells MCWD-29 and MCWD-31. (Section 5.3.4, Historical Progression of Seawater Intrusion, p. 49). **HWG Comment:** Figure 5-29 indicates TDS concentrations of approximately 400 mg/L during 2019 in MCWD-29 and MCWD-31. Review of the 2019 AEM Survey Report Table 4-1 shows that AEM based TDS concentrations in the zone screened by these wells is estimated to be greater than 1,000 mg/L (about three times the field measured concentrations). Based on analysis (AEM data is a major data source of mapping sweater intrusion in the GSP) and relationships between chloride and TDS established in the GSP (e.g., chloride concentrations of 500 mg/L equate to TDS concentrations of approximately 1,000 mg/L), it seems that MCWD wells MCWD-29 and MCWD-31 should be included within the area of mapped seawater intrusion. In fact, this discrepancy demonstrates how interpretation of AEM data with regard to water quality can result in significant errors relative to field measured data. Interpreted AEM data has also been shown to significantly underpredict TDS/chloride concentrations (e.g., HWG, April 2019) is some areas.	A comparison of AEM data and water quality data from wells MCWD-29, MCWD-30 and MCWD-31 is presented on Figure 5-27. As shown on these figures, the AEM data and water quality data from these wells is very consistent and show that these wells are primarily screened within zones that have TDS concentrations < 500 ug/L. Some of the deeper screens from these wells do extend into areas where resistivity estimates are in the moderate range and could be indicative of higher salinity groundwater or higher amounts of clay. This phenomenon is also observed at MCWD-34, where groundwater extracted from this well has lower TDS concentrations than AEM data suggest. As stated in section 5.3.1.2 Geophysical Data: "Stanford study found that very high resistivity (greater than 25 ohm/cm) or very low resistivity (smaller than 5 ohm/cm) are indicative of fresh groundwater and high salinity groundwater and, respectively. Moderate AEM resistively in the range of 5 to 25 ohm/cm can be indicative of either higher salinity or higher amount of clay in subsurface materials, thus the exact water quality associated with these resistivity values is more difficult to discern." Due to this limitation, AEM data is better at detecting areas of fresh groundwater and can over predict salinity in some areas due to the presence of clay sediments. However, as previously discussed, significant groundwater quality data exists within the Monterey Subbasin, which supports AEM results. All of these data have been integrated to develop the hydrogeologic conceptual model and map the extent of seawater intrusion within the Subbasin.
31. The GSP relies on a study conducted by WRA Environmental (2020) to conclude that 19.51 acres of aquatic and upland biological communities at six ponds are dependent upon groundwater (Section 5.7.1, Groundwater Dependent Ecosystems, Coastal Vernal Ponds within the City of Marina, p. 68). **HWG Comment:** We note that the five authors of the report by WRA Environmental are all biologists, with no apparent contribution from a hydrogeologist to help evaluate groundwater conditions and dependence of the plant communities on	The Marina ponds have been identified in DWR's NC Dataset as potential GDEs (https://gis.water.ca.gov/app/NCDatasetViewer/). Based on information from the WRA study and the NC dataset, the GSP has reasonably identified these ponds as GDEs or potential GDEs. Pursuant to the *Nature Conservancy's Best Practices for Using the NC Dataset* (dated July 2019), "The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network." Per the Identifying GDEs

HWG Comments	Responses
groundwater. The only investigation of groundwater in the report was digging a hole to 14 inches in depth to look for soil saturation; however, these field efforts are inadequate to determine groundwater conditions at the sites because there may be shallow fine-grained sediment layers supporting perched/saturated soils in the upper few feet of soil. The WRA report also cites the fact that their field efforts were conducted in June 2020, well after the end of the rainy season, and water was still observed in most of the ponds (implying it must be groundwater). However, review of monthly precipitation data for the 2019 and 2020 water years indicates the 2019 year was very wet (133% of normal) and the 2020 water year was wet (105% of normal). In addition, heavy rainfall occurred in March and April 2020 (about 6.5 inches or close to half the average annual rainfall) with smaller amounts of rainfall in May and June; therefore, it would be expected that surface runoff remained in the ponds with near surface saturation at the time of WRA's June 2020 site visits. We also note that the WRA Report relies on other studies such as Formation Environmental (April 2020) and the draft City of Marina GSA GSP (2020). The HWG has previously commented on these studies, and Geoscience/AECOM conducted the most recent study on the vernal pools (HWG, November 2019; Geoscience and AECOM, August 18, 2020). Summary Geoscience/AECOM comments on the Formation Environmental TM included: 1) very limited use of available groundwater data from MPWSP MW-4 and MW-7 to one point in time without considering entire record and impact of agricultural irrigation return flows in immediate vicinity; 2) relies solely on ET data to justify conclusion that Armstrong Ranch Ponds are groundwater dependent without consideration of alternative water sources such a seasonal surface water from rainfall; 3) failure to account for perched aquifer conditions underlying area; 4) failure to account for effects of urbanization surrounding six ponds in city of Marina that caused ponds to become primarily reliant of surface water runoff and leading to ponds becoming perennial. Furthermore, all six ponds in the Marina area are not hydraulically connected to the coastal Dune Sand Aquifer (thus, pumping from coastal Dune Sand Aquifer will not	under SGMA – Best Practices for Using the NC Dataset dated July 2019 provided by the Nature Conservancy.

HWG Comments	Responses
affect them); and all ponds received surface discharge from storm drains that empty into the ponds. Several ponds were found to have hardpan layers beneath them that limit percolation and likely account for WRA observations of shallow saturation. In addition, water quality data suggest that ponds are more influenced by stormwater runoff than groundwater from the perched aquifer system. Overall, it was found that the Formation Environmental study is fundamentally flawed , misrepresents potential impacts on ponds from pumping in the coastal Dune Sand Aquifer, and does not consider all available evidence concerned the nature of these pond resources and potential impacts to them from pumping. HWG comments on the City of Marina GSA Draft GSP state, "the fact that nearby GDEs are seasonally flooded and have a seasonal nature to them (and are associated with "a lens of less pervious soil") suggests a surface water source is most likely sustaining vegetation in these areas. The GSP evaluation to determine if potential GDEs are actual GDEs did not consider that shallow groundwater in these nearby potential GDE areas is saline or the likelihood that fresh surface water is the primary sustaining factor for these areas and (which means they are not GDEs)."	
32. We note that the City of Marina Draft GSP stated the following with regard to pumping from Marina Coast Water District Deep Aquifer wells, "The combined extraction from these wells was approximately 1,823 AFY in 2015, and is forecast to increase to 3,905 AFY by 2035…" (Section 3.1.8, page 3-17). **HWG Comment:** While the Monterey Subbasin GSP comments on the impacts of increasing pumping from the Deep Aquifer in the adjacent 180/400-Foot Aquifer Subbasin, it is silent on the issue of increased pumping from existing (and potential future new) MCWD Deep Aquifer wells. The cited MCWD Deep Aquifer pumping numbers represent a greater than doubling of the amount of current MCWD pumping from the Deep Aquifer, a pumping amount that already results in Deep Aquifer water levels within Monterey Subbasin on the order of 50-100 feet below sea level. Such increased pumping from the Deep Aquifer by MCWD and others is likely not sustainable.	Impacts of potential future groundwater extraction will be included in the Water Budget Chapter of the GSP.

HWG Comments	Responses
33. We note that the City of Marina Draft GSP stated, "In the Monterey Subbasin, groundwater demand from the Deep Aquifer by MCWD to supply the City of Marina is expected to increase….however, the increase is projected to be within MCWD's allocated pumping rights." (Section 3.3.10.4, page 3-69). **HWG Comment:** Regardless of the validity of allocated pumping rights (which is yet to be determined), it remains unclear if the proposed MCWD increase in pumping from the Deep Aquifer is sustainable. In addition, the increased pumping from the Deep Aquifer to the east to support agricultural expansion is based on overlying rights, not allocated (paper water) pumping rights, and are thereby presumably superior to MCWD rights.	Impacts of potential future groundwater extraction will be included in the Water Budget Chapter of the GSP. SGMA does not establish groundwater rights. HWG's apparent legal opinion regarding the MCWD's pumping rights is not relevant to the GSP.
Monterey Subbasin GSP Comment Log (Prepared by SVBGSA)	
1. In Comment 41 (dated 1/7/21) Tina Wang states, "…There is one thing we pointed out in that chapter, is the dune sand aquifer and the upper 180 foot aq is not SWI intruded, it is fresh." **HWG Comment:** As pointed out in our comments on GSP Chapters 4 and 5, the Fort Ord Site Conceptual Model (i.e., continuous intermediate aquitard within 180-Foot Aquifer and lack of a 180/400-Foot Aquitard) does not apply in northern Monterey Subbasin. Furthermore, available field data indicate that the Dune Sand Aquifer and upper portion of the 180-Foot Aquifer are seawater intruded (chloride greater than 500 mg/L) for a significant distance inland from the coast in the northern Monterey Subbasin and Southern 180/400-Foot Aquifer Subbasin. We also note that EKI's (and others) definition of fresh water in many previous documents related to the MPWSP has been TDS up to 3,000 mg/L; however, HWG have shown such levels of TDS also have greater than 1,000 mg/L chloride in the area, which is far in excess of the 500 mg/L standard applied by MCWRA for seawater intrusion. The Monterey Subbasin GSP uses AEM data outside of Monterey Subbasin (i.e., in southern 180/400-Foot Subbasin) to claim the presence of this so-called fresh water, yet actual field data show seawater intrusion has occurred at the coast and for	See responses to HWG Chapter 4 comments 5 and 7, and HWG Chapter 5 Comments 3 and 19.

HWG Comments	Responses
a significant distance inland in this area (see HWG, 2017).	
2. In Comment 44 (dated 1/7/21) Derrik Williams responds to the commenter (Bob Jaques) that, "We have discussed the AEM data with some members of the blue ribbon panel…the didn't have too many concerns.' **HWG Comment:** If the commenter is referring to the Hydrogeologic Working Group, this statement by Derrik Williams is incorrect. The HWG has many concerns about the hydrogeologic interpretation of the AEM data and has documented our concerns in numerous documents (e.g., HWG, 2017; HWG, 2018; HWG, January 2019; HWG, March 2019; HWG, April 2019; HWG, June 2020).	See response to HWG Chapter 4 comment 9.

11/1//2021 – Comments on Monterey Subbasin Public Draft GSP Chapter 6

"This letter is submitted on behalf of California American Water and provides comments on Chapter 6 (Water Budget) for the Public Draft Monterey Subbasin GSP Chapter 6 released on September 3, 2021. It also includes a brief review of how previous comments by the Hydrogeologic Working Group (HWG) on Monterey Subbasin GSP Chapters 4 (HCM) and 5 (Groundwater Conditions), which are attached to this comment letter, were not addressed in the recently released Public Review Draft versions of these chapters. Detailed comments are provided along with a summary of the main comments."

SUMMARY OF COMMENTS

The Monterey Subbasin GSP emphasizes in several places that subbasin sustainability is dependent on adjacent subbasins becoming sustainable. While there is some interdependence between subbasins that may impact the sustainability of adjacent subbasins, the GSAs in the Monterey Subbasin should focus on their role in making the Subbasin sustainable. This is best achieved by comparing groundwater recharge (just the vertical components of flow from the soil moisture balance, not including subsurface inflows form adjacent subbasins) in the Marina-Ord Area to groundwater pumping in the Marina-Ord Area. In addition, there needs to be excess groundwater recharge over and above total pumping for significant outflow to the ocean to prevent seawater intrusion.

A summary of several other major Chapter 6 comments includes:

- Groundwater model documentation is key to understanding the water balance, but is not included in available Public Draft GSP documents made available for review;
- Soil moisture budget accounting model documentation is key to understanding the water balance, but is not included in available Public Draft GSP documents made available for review;
- The surface water system water budget required under SGMA is not provided;
- There is a major inconsistency in estimated net subsurface inflow between the Monterey Subbasin and the 180/400 Foot Aquifer Subbasin presented in the GSPs for the two subbasins (i.e., 12,500 AFY vs. 3,000 AFY);
- The extent of seawater intrusion within the Monterey Subbasin has expanded over the historical period covered by the GSP, which is in contrast to statements/assumptions in the GSP;
- Some of the boundary conditions used in the groundwater model for future project scenarios are not realistic and are inconsistent with the 180/400 Foot Aquifer Subbasin GSP;
- The GSP Marina-Ord Area water balance indicates that increases in groundwater pumping for the future project scenario are not realistic and are not sustainable, because they exceed Marina-Ord Area groundwater recharge and do not allow for outflow to combat seawater intrusion;
- Future project scenarios should be more conservative and should not assume groundwater recharge will increase in the future by 10 to 20% due to climate change;
- Groundwater model results indicate that MTs and MOs will likely not be achieved in the Monterey Subbasin if realistic boundary conditions are applied; and
- The sustainable yield estimate of 4,400 to 9,900 AFY for the Marina-Ord Area is significantly overestimated, and will likely have detrimental impacts on adjacent subbasins (i.e., the Seaside Basin and the 180/400 Foot Aquifer Subbasin)."

<u>Please see responses below for details.</u>

LSCE Comments	Responses
Section 6.1 (Water Budget Method)	
1. The GSP states that the water budget information is based on use of a groundwater flow model developed for the subbasin (p. 6-8). **Comment:** The model documentation (Appendix 6B) was not provided for review; thus, it is not possible to provide complete comments on the water balance without being able to review documentation for the model used to produce the water balance. Without the supporting documentation, stakeholders and the public are not able to adequately comment on the relevant issues.	Appendix 6B, which contains the model documentation, has been made available. It was uploaded to MCWD's website on 11/10/2021.
2. The GSP states that a soil moisture budget (SMB) accounting model is used to estimate groundwater recharge (p. 6-10). **Comment:** While Appendix 6-A provides some tables with output data from the SMB, no model documentation is provided. Thus, it is not possible to provide complete comments on the water balance without being able to review documentation for the SMB model used to provide key input to the groundwater model and water balance. Without the supporting documentation, stakeholders and the public are not able to adequately comment on the relevant issues.	Appendix 6B, which contains the model documentation, has been made available. It was uploaded to MCWD's website on 11/10/2021.

3. The GSP states, "As discussed in Appendix 6B, the MBGWFM has been calibrated against 30,354 historical water level measurements to achieve normalized calibration error statistics of less than 2% and thus adequately represents the historical conditions of the Basin. Therefore, it is appropriate to use the MBGWFM to estimate water budgets for the Monterey Subbasin." (p. 6- 10). **Comment:** Appendix 6B was not provided for review. While good calibration to water levels is important, it does not in and of itself validate use of the model for producing a valid water balance. Other key considerations include the fact that simulated water levels and subsurface inflows/outflows can be highly variable depending on boundary conditions. Thus, various combinations of recharge, discharge, aquifer parameters, and boundary conditions can produce similarly good model calibrations to water levels (i.e., models are non-unique). For example, a groundwater model with less vertical recharge could produce a good calibration to groundwater levels with a different set of aquifer parameters and/or boundary conditions. Therefore, additional justification is needed for use of the model for water balance output, such as comparison to adjacent subbasin water balances and the amount of vertical recharge (e.g., precipitation recharge, excess irrigation recharge) per acre. For example, the 180/400-Foot Aquifer Subbasin historical water budget has vertical recharge amounting to 0.22 ft/acre compared to the Monterey Subbasin historical water budget with vertical recharge of 0.33 ft/acre, or 50% greater vertical recharge than the immediately adjacent 180/400-Foot Aquifer Subbasin.	Appendix 6B, which contains the model documentation, has been made available. It was uploaded to MCWD's website on 11/10/2021. There is inherent uncertainty in any basin water balance, especially in basins where multiple aquifers exist and where significant cross-boundary flows are known to occur between adjacent, hydraulically connected subbasins. Similarly, nearly all numerical groundwater flow models are considered to be "non-unique", as they are based on imperfect information regarding aquifer parameters and their spatial distribution, time-varying boundary conditions, and spatiotemporal stresses such as recharge and pumping. Uncertainties and limitations of the MBGWFM are described in detail in Section 6.7 and Appendix 6B. With this in mind, significant effort was expended to ensure that aquifer parameters (e.g., hydraulic conductivities and storage coefficients) were calibrated to measured values and that estimated recharge rates were consistent with other models developed for the Monterey Subbasin and surrounding areas. Section 4 of the model documentation (Appendix 6B) details the methodologies and datasets used to inform model calibration. It is unreasonable to directly compare recharge estimates from the MBGWFM to estimates provided in the 180/400-Foot Aquifer GSP because: (1) land use conditions are substantially different between the two subbasins (e.g., the Monterey Subbasin is predominantly undeveloped and low-density residential land except for in the City of Marina, whereas the 180/400-Foot Aquifer Subbasin has a large agricultural and urban footprint); (2) precipitation rates differ substantially between the two subbasins; and (3) the recharge estimates were developed using entirely different methodologies and, notably, water budgets presented in the 180/400-Foot Aquifer GSP were not informed by a numerical model (see reply to comment 6 below). As part of MBGWFM calibration, recharge rates output from the soil moisture balance model (SMB) were compared to analogous estimates produced for the Monterey Subbasin by the Farm Package of the Salinas Valley Integrated Hydrologic Model (SVIHM), which is being used to develop

LSCE Comments	Responses
	updated water budget estimates for the 180/400-Foot Aquifer Subbasin GSP. Comparison between the SMB and SVIHM indicates that average Basin-wide recharge rates calculated from the SMB are +12% higher than those calculated from the SVIHM over like timeframes. However, when looking at normalized recharge rates, it appears that the SMB and SVIHM track very closely in most areas of the Basin. For example, the SMB calculated ~25.3% of total precipitation and applied water as contributing to recharge in the Corral de Tierra Management Area, compared to ~25.6% calculated from the SVIHM. The most significant difference between the two models is within urban areas, where the SMB calculates ~11.6% recharge of precipitation and applied water compared to ~5.8% calculated from SVIHM. This discrepancy may in part be explained by the fact that SVIHM does not account for deliveries from municipal water suppliers or leakage from water conveyance systems within urban areas of the basin in its recharge calculations. Therefore, it appears the discrepancy in Basin-level recharge between the two models can be primarily explained by differences in input datasets and assumptions between the two models rather than fundamental differences in recharge calculation methodologies. See Appendix 6B for a more detailed description of the SMB and comparison of estimated recharge rates to other existing models.
4. The GSP states, "To quantify all required water budget components as specified in the GSP Emergency Regulations (CCR § 354.18(b)), this GSP presents results from both the SMB for the land surface system and the MBGWFM for the groundwater system." (p. 6-11). **Comment:** The GSP Emergency Regulations (CCR § 354.18(b.1)) require, "Total surface water entering and leaving a basin by water source type." A surface water budget is not provided in Chapter 6; this would include total streamflow and any imported water entering and leaving the Monterey Subbasin.	Comment noted. An updated version of Chapter 6 will be provided that includes a tabular summary of total surface water entering and leaving a basin by water source type over the historical and current water budget period.
Section 6.2 (Water Budget Components)	
5. The GSP states that inter-basin cross-boundary flows (e.g., between the Monterey Subbasin and the 180/400 Aquifer Subbasin) are based on model general head boundary conditions (p. 6-15). **Comment:** The details of the general head conditions used (i.e., heads, conductance) are not provided and cannot be reviewed. Presumably such details would be provided in the Model Documentation in Appendix 6B if it were made available for public review.	Appendix 6B, which contains the model documentation, has been made available. It was uploaded to MCWD's website on 11/10/2021.
Section 6.4 (Historical and Current Water Budget)	

LSCE Comments	Responses
6. GSP Table 6-1 provides historical and current groundwater water budget results (p. 6-20). **Comment:** The historical and current Monterey Subbasin water budgets show net subsurface outflows of 12,265 to 12,565 AFY to the 180/400-Foot Aquifer Subbasin. Review of the DWR-approved GSP for the 180/400-Foot Aquifer Subbasin shows historical and current water balance net subsurface inflows from the Monterey Subbasin of 3,000 AFY. Thus, there is a large discrepancy between the two GSPs regarding subsurface cross-boundary flows. If the Monterey Subbasin GSP cross- boundary flows are correct, the difference between inflows and outflows for the historical groundwater budget for the 180/400-Foot Aquifer Subbasin GSP changes from -12,900 AFY to -3,635 AFY, which has significant implications for the 180/400-Foot Aquifer Subbasin GSP. In general, this uncertainty in cross-boundary flows also points out that subbasin sustainability should be based (primarily) on balancing the vertical components of recharge and discharge. This eliminates the uncertainty regarding cross-boundary flows (and associated dependency) in evaluating projects/management actions needed to achieve sustainability.	As discussed in the Monterey GSP, a lot of care was taken to assess cross boundary flows and accurately represent conditions in adjacent subbasins. Estimated cross boundary flows between the Monterey Subbasin and the 180/400-Foot Aquifer Subbasin are significantly higher than those presented in the 180/400-Foot Aquifer GSP. This discrepancy is well founded. Due to time constraints, historical and current water budgets presented in the 180/400-Foot Aquifer GSP were developed based on data and analyses aggregated from previous reports and other available sources. No numerical modeling effort was completed to develop the historical or current water budget. The limitations of the historical water budget analyses included in the 180/400-Foot Aquifer GSP are well acknowledged within the GSP, and additional analyses are being conducted as part of the 5-year review process. In fact, as noted in the 180/400-Foot Aquifer GSP, the estimated inflow from the Monterey Subbasin of 3,000 AFY/year was taken from a Montgomery Watson document produced in 1997. This document generally looks at data that pre-dates the Historical Period evaluated in the Monterey GSP (i.e., water years 1999 through 2018). It is based on a very limited dataset and does not reflect conditions within these subbasins over the last 15 years. The MCWD GSA and SVBGSA collaborated on development of the MBGWFM including boundary conditions along the boundary of the 180/400-Foot Aquifer Subbasin and beneath the Salinas River. Additional information and documentation of collaborate efforts between the agencies as part of MBGWFM development has been added to the water budget section and as Appendix 6C.

LSCE Comments	Responses
7. A footnote to Table 6-1 states, "All seawater inflows from the ocean are presumed to leave the Monterey Subbasin across the 180/400 Foot Aquifer Subbasin boundary, as evidenced by no observed expansion of the seawater intrusion front in the Monterey Subbasin over the historical time period." (p. 6-20). This issue is also discussed in the first bullet at the top of page 6-23, and first bullet at the top of page 6-24. **Comment:** Review of seawater intrusion maps prepared by MCWRA indicates this statement/conclusion is not correct – the seawater intrusion front in Monterey Subbasin has expanded over the historical time period.	As discussed in Chapter 5, no evidence of expansion of the seawater intrusion front has been observed in the Monterey Subbasin during the historical period (2004 to 2018). MCWRA maps are developed on the basis of chloride data which is collected intermittently from a limited number of wells (see Figure 5-27 for locations of wells with post-2015 chloride data). As part of the Monterey GSP effort, specific conductance and TDS data collected from Fort Ord Wells was analyzed and utilized to evaluate the seawater intrusion front. As presented in Appendix 5A, a very high correlation exists between TDS, chloride and specific conductance in groundwater within this subbasin.
8. GSP Figure 6-4 (p. 6-21) indicates subsurface flow occurs from the Corral de Tierra Area to the Marina Ord Area. **Comment:** Review of topography and studies by others (e.g., Geosyntec, 2007) indicates essentially no flow between the two Areas, but rather subsurface flow from the Corral de Tierra Area strictly to the 180-400 Foot Aquifer Subbasin. The water balance for Marina-Ord Area assumes such subsurface inflow amounts to 1,544 AFY, but this is likely not the case.	As indicated by the Geosyntec study, significant groundwater flow from the Corral de Tierra Area to the 180/400 Foot Aquifer Subbasin exists. The Monterey Subbasin Groundwater Flow Model estimates that, on average, approximately 3,632 AFY of groundwater flows from the Corral De Tierra Area WBZ to the 180/400 Foot Aquifer Subbasin over the historical period. Groundwater gradient map developed as part of the GSP show that some groundwater flows between the Coral De Tierra Area and the Marina-Ord Area, which is estimated at 1,544 AFY over the historical period. However, as discussed in the GSP, there are few wells along the boundaries between the Corral De Tierra Area and the 180/400 Foot Aquifer Subbasin and the Marina Ord Area. The absence of such data has been identified as a data gap. Additional wells are planned in these areas to further assess these cross-boundary flows.
9. The GSP states that outflows to the ocean occur from the Dune Sand Aquifer (p. 6-22). **Comment:** The HCM and groundwater elevation contour maps indicate that the Dune Sand Aquifer and 180- Foot Aquifer merge inland of the coast where the FO-SVA aquitard pinches out and the combined groundwater flow moves inland. The GSP presents no evidence of outflow to the ocean.	As shown on Figures 5-1 and 5-2, water levels in the Dune Sand Aquifer are above mean sea level. Although much of the water from the Dune Sand aquifer returns to the subbasin via the Upper 180-Foot aquifer as illustrated in Figure 4-19, it is anticipated that some discharge to the ocean occurs. However, the freshwater/ocean water interface is highly complex in this heterogenous environment and dual density modeling has not been conducted. The modeling that has been conducted focuses on larger basin water budget issues that are the focus of the GSP. Although relevant to the California American Water Monterey Peninsula Water Supply Project, the intricacies of this freshwater/seawater interface are not explored as part of this GSP.

LSCE Comments	Responses
10. The GSP notes that estimated net annual inflows/outflows between the Monterey Subbasin and the Seaside Subbasin are consistent with the estimates from the Seaside Basin Groundwater Flow Model. However, this same statement of consistency is not made by the GSP for estimated net annual inflows/outflows between the Monterey Subbasin and the 180/400 Foot Aquifer Subbasin. **Comment:** As noted above, there is a major discrepancy between the 3,000 AFY of net inflow to the 180/400 Foot Aquifer Subbasin from the Monterey Subbasin estimated in the 180/400 Foot Aquifer Subbasin GSP versus the 12,365 AFY of net inflow to the 180/400 Foot Aquifer Subbasin estimated in the Monterey Subbasin GSP.	See Response to Comment 6.
11. The GSP notes that the Dune Sand Aquifer has seaward gradients that result in 534 AFY of net outflow to the ocean (p. 6-23). **Comment:** The groundwater elevation contour maps presented in Chapter 5 do not include data points near the coast and provide no evidence of outflow to the ocean. In fact, other data indicate there is no outflow to the ocean from the Dune Sand Aquifer as described above.	See response to comment 9.
12. The GSP states that groundwater elevations in the 180/400 Foot Aquifer Subbasin are 40 feet below mean sea level (MSL) in the 180 and 400-Foot Aquifers and 100 feet below MSL in the Deep Aquifer (p. 6-24). **Comment:** It should also be noted here that groundwater elevations in the Monterey Subbasin are 20 to 30 feet below MSL in the 180 and 400-Foot Aquifers and 50 to 70 feet below MSL in the Deep Aquifer.	This information is presented on the figures of the GSP. The purpose of this statement is to note that water levels in the 180/400 Foot aquifer subbasin are lower than those in the Monterey Subbasin, which is consistent with the HCM and cross-boundary flow estimates presented in the GSP.

LSCE Comments	Responses
13. Figure 6-5 (p. 6-27) shows an area of seawater intrusion in Monterey Subbasin with arrows showing groundwater flow directions in this area. The text describes these arrows as, "…the general direction of presumed freshwater and seawater cross-boundary flows…" (p. 6-28). The GSP also states, "…it is difficult to predict if seawater inflows from the ocean will continue to pass through the Monterey Subbasin into the 180/400 Foot Aquifer subbasin as they did during the historical period." (p. 6-42). **Comment:** The area of seawater intrusion does not match the sea water intrusion maps prepared by MCWRA and does not distinguish seawater intrusion in the 180-Foot Aquifer vs. 400-Foot Aquifer as done by MCWRA. In addition, the groundwater flow direction arrows within the zone of seawater intrusion are incorrect and do not correlate with the groundwater elevation contours included on the map, which indicate a portion of the groundwater within the seawater intrusion zone flowing towards the middle inland portion of Monterey Subbasin. It is not clear why the groundwater flow directions shown are based on "presumed" directions rather than the flow arrows that would be derived based on actual groundwater elevation contour lines shown on the figure.	See response to comment 7.
14. The GSP states, "…pumping in the Corral de Tierra Area is estimated using the known data, and may be missing a significant amount of pumping." (p. 6-33). **Comment:** If a significant amount of pumping is not accounted for in the Corral de Tierra Area, then subsurface outflow is significantly overestimated.	This comment is correct. As stated in the GSP, the magnitude of pumping in the Coral De Tierra has been identified as a data gap and additional information will be obtained as part of ongoing GSP efforts. Such information will be incorporated into future model updates and cross-boundary flows will be reevaluated.
Section 6.5 (Projected Water Budget)	
15. Projected water demands for the MCWD service area are estimated to increase from 3,367 to 8,314 AFY, and it is assumed that increased pumping would be divided evenly between the 180 and 400 Foot Aquifers and the Deep Aquifer based on historical MCWD operations (pp. 6-37 and 6-38). **Comment:** Given the evolution of MCWD pumping distribution between the Deep Aquifer and shallower aquifers to the point where Deep Aquifer pumping has apparently increased to become more than two-thirds of total MCWD pumping in recent years, it is apparent that the 180 and 400 Foot Aquifers cannot accommodate the proposed future pumping increases stated in the GSP. The future model scenario should assign all future increases in pumping to the Deep Aquifer. This pumping distribution will likely have a major effect on future scenario model results.	Where additional pumping will occur is unknown. Simplifying assumptions have been made in the GSP. GSP updates will evaluate the impacts of additional pumping as it is proposed.

LSCE Comments	Responses
16. The GSP states that model boundary conditions used in future scenarios include: minimum thresholds (MT), measurable objectives (MO), and seawater intrusion protective boundary conditions (p. 6-38). **Comment:** The seawater intrusion protective boundary conditions are not defined in terms of what they are or how they were derived, or how likely they are to occur. Since they are not provided in GSPs for adjacent subbasins as likely to occur, they do not seem appropriate to use.	As described in Chapter 6 of the GSP, seawater intrusion protective boundary conditions represent minimum groundwater levels that would be required to stop seawater intrusion within the 180/400 Foot Aquifer subbasin, in the absence of an extraction or injection barrier. The seawater intrusion protective heads have been calculated on the basis of the Ghyben-Herzberg Relation described in Section 5.3.2 of the GSP. The actual value for each aquifer and climate scenario varies based upon the average depth of the aquifer and the estimated value of mean sea level under the assumed future climate scenario. The detailed description of freshwater equivalent heads was included in Appendix 6B. Given that groundwater extraction or injection barriers will require hundreds of millions of dollars to construct, it is very conceivable that they will not be completed and pumping reductions and in lieu recharge will used to reach sustainability. Such projects and management actions are also identified in the 180/400 Foot Aquifer Subbasin GSP Measurable Thresholds for seawater intrusion established in the 180/400 Foot Aquifer Subbasin GSP, do not allow expansion of the seawater intrusion front. As such, in the absence of injection/extraction barriers groundwater levels will need to be raised to seawater protective levels to stop further seawater intrusion and meet Measurable Thresholds for seawater intrusion in the 180/400 Foot Aquifer Subbasins. Such groundwater levels would be achieved through pumping reductions and/or in lieu recharge which are included as potential projects and management actions in the 180/400 Foot Aquifer GSP. As such, this scenario provides insights regarding the impacts of such potential future boundary groundwater conditions on the Monterey Subbasin.

LSCE Comments	Responses
17. The GSP states that for the MT Boundary Conditions in the projected model scenario run, "Groundwater levels in RMS wells located near the Monterey Subbasin are raised from 2018 model predicted values to water level MTs established in the 180/400 Foot Aquifer GSP…" (p. 6-38). **Comment:** Review of water level data from MCWRA indicates that 2015 to 2016 water levels were generally lower than 2018 water levels. The 180/400-Foot Aquifer Subbasin GSP set MTs one foot above 2015 water level elevations. Thus, it is not clear why model-predicted 2018 water levels in boundary condition areas would need to be raised to be at MT levels established in the 180/400-Foot Aquifer Subbasin unless model-predicted groundwater elevations for 2018 were substantially lower than observed values. If model-predicted values are substantially lower than observed values in boundary condition areas, the model would likely significantly overestimate groundwater outflow from the Monterey Subbasin to the 180/400-Foot Aquifer Subbasin.	Comment noted. In all cases, water levels at general head boundary cells along the northern MBGWFM boundary were <u>adjusted</u> from Fall 2018 levels to MT levels defined at 180/400-Foot Aquifer RMS wells. For certain wells, this may result in an increase in water levels relative to Fall 2018 conditions, while in other wells this may result in a decrease in water levels relative to Fall 2018 conditions. This sentence has been reworded to clarify that water levels "are <u>adjusted</u> from 2018 model predicted values to water level MTs established in the 180/400-Foot Aquifer GSP."
18. The GSP states that seawater intrusion protective elevations are, "…consistent with the MTs for seawater intrusion established in the 180/400 Foot Aquifer GSP." (p. 6-39). **Comment:** Based on this statement, it is not clear how seawater intrusion protective elevations differ from MT elevations. Several figures in the GSP suggest seawater intrusion protective elevations are much higher than MT elevations.	See response to comment 16.
19. The GSP Project Scenario calls for increased use of recycled water from 600 AFY in 2023 to 5,495 AFY in 2040, with total demand in 2040 and beyond of 10,955 AFY. **Comment:** This Project scenario assumes that recycled water can provide 50% of total water demand for MCWD, which is likely unrealistic. In addition, other documents (MCWD Urban Water Master Plan, MCWD Water Supply Master Plan) indicate future recycled water use would be limited to no more than 1,500 AFY.	This project consists of using purified recycled water for indirect potable reuse (IPR). As discussed on page 9-54 under "IPR in Monterey Subbasin", IPR includes injecting non-potable water into a groundwater aquifer for later recovery. This generates potable water that can meet a larger portion of MCWD's demand beyond irrigation needs.
20. The GSP states, "…the projected water budget results indicate that the climate scenarios have a much smaller impact on changes in storage and groundwater levels within the subbasin than the identified boundary conditions." (p. 6-43). **Comment:** While this statement may be true relative to horizontal groundwater flows, it is not true with regard to vertical groundwater recharge that increases substantially (about 10 to 20%) under future climate change scenarios. Additional projected model runs should be made using historical groundwater recharge amounts due to the significant uncertainty in future groundwater recharge increases.	Results for model runs for 2030 and 2070 climate scenarios are included in the GSP. See Chapter 6 and Appendix 6B.

LSCE Comments	Responses
21. GSP Table 6-5 (Comparison of Projected Water Budget Results Under "No Project" Scenarios with Variable Boundary Conditions and 2030 Climate Condition, Marina-Ord Area WBZ) shows 8,767 AFY of groundwater pumping versus 6,823 AFY of total groundwater recharge (p. 6-45). **Comment:** Under these scenarios groundwater pumping exceeds groundwater recharge by approximately 2,000 AFY and is not sustainable.	As discussed in the GSP under the future No Project Scenario, groundwater pumping does exceed groundwater recharge and the GSP concludes that MTs will likely not be met under this scenario. Potential projects have been identified to meet MTs and MOs within the groundwater subbasin under increased demands. The authors premise that groundwater recharge is equivalent to the sustainable yield of a groundwater subbasin is a reasonable argument, but is not articulated under SGMA.
22. The GSP states, "…ocean inflows into the basin also decrease as water levels at this boundary increase from MTs, to MOs, and to SWI protective elevations…However, there is little reduction in net ocean inflows between the historical water budget and the projected baseline water budgets under MT boundary conditions or MO boundary conditions." (p. 6-48). **Comment:** This statement would seem to indicate that ocean inflows are driven by Monterey Subbasin groundwater elevations.	This comment seems to ignore the fact that water levels in the Monterey Subbasin are impacted by water levels in the adjacent 180/400-Foot Aquifer subbasin, and vice-a-versa. While net ocean inflows are similar between the historical and projected baseline scenario water budgets, the projected baseline scenario water budget also assumes an average pumping rate of 8,767 AFY in the Marina-Ord area, compared to 4,346 AFY in the historical model. This indicates that, if the 180/400-Foot Aquifer Subbasin were able to maintain MT or MO water level conditions, MCWD could pump at least twice as much from its subbasin without causing further increases in ocean inflows as this additional pumping would instead be offset by decreased outflows to the 180/400-Foot Aquifer Subbasin.
23. The GSP states, "…projected water budgets also indicate that substantial groundwater outflows from Monterey Subbasin continue to occur into the 180/400-Foot Aquifer Subbasin under MT and MO boundary condition scenarios." **Comment:** It should be determined how much of this groundwater outflow across Subbasin boundaries is due to sea level rise.	The MBGWFM currently does not include a dual-density groundwater flow component to explicitly simulate seawater intrusion in the Basin (see Appendix 6B), thus making a detailed analysis of projected seawater intrusion rates and spatial migration patterns impractical. However, as described in Section 9.8.6, MCWD and SVBGSA plan to coordinate to convert the MBGWFM into a seawater intrusion model within the first 5-years of SGMA implementation. A more detailed analysis of seawater intrusion rates and spatial trends, including an analysis of sea level rise impacts on cross-boundary flows, will be completed upon development of this model.
24. With respect to the Marina-Ord Area, the GSP states, "…these projected water budget results indicate that this management area will not be in overdraft if adjacent basins are managed sustainably and SMCs are achieved." (p. 6-50). **Comment:** Given that pumping exceeds recharge by 2,000 AFY in in the Marina-Ord Area per Table 6-5, it is not clear how this Area can be considered to not be in overdraft under projected future conditions.	See response to comments 21 and 19.

LSCE Comments	Responses
25. The GSP states, "…it is difficult to predict if…changes in boundary conditions and increased extraction in the subbasin could cause saline groundwater from the 180/400 Foot Aquifer subbasin or ocean to flow further inland within the Monterey subbasin. It is noted that MCWD has significant operational flexibility regarding rates of extraction from its wells and could potentially modify the location and depth at which groundwater is extracted to limit such impacts." (p. 6-50 to 6-51). **Comment:** The groundwater model should be able to provide some indication of the potential for saline water from the ocean to flow further inland within the Monterey Subbasin. As discussed in other comments, MCWD does not appear to have operational flexibility on depth of extraction and additional pumping is likely to occur from the Deep Aquifer.	See response to Comment 16.
26. In reference to Figure 6-8, the GSP states, "This figure indicates that variable climate conditions have limited impacts on projected water levels in RMS wells relative to boundary condition scenarios." (p. 6-51). **Comment:** This figure and the associated statement here are misleading with regard to the impacts of variable climate conditions assumed in the future scenario. The future climate change assumptions result in an increase in groundwater recharge ranging from 10 to 20%, which is highly uncertain. A better approach would be to assume groundwater recharge in the future will be similar to historical groundwater recharge. The assumption of increased future groundwater recharge may exacerbate overdraft that is already predicted to occur even with the assumed increased in groundwater recharge (see Table 6-5 where groundwater pumping exceeds future groundwater recharge by approximately 2,000 AFY).	Per GSP regulations 23-CCR §354.18(e), *"Each Plan shall rely on the best available information and best available science to quantify the water budget for the basin in order to provide an understanding of historical and projected hydrology, water demand, water supply, land use, population, <u>climate change</u>, sea level rise, groundwater and surface water interaction, and subsurface groundwater flow"*. As further described in Appendix 6B, EKI utilized the methodology and datasets provided in DWR's *Guidance for Climate Change Data Use During Groundwater Sustainability Plan Development* (DWR, 2018) to estimate climate change impacts to ET and precipitation, which directly informed corresponding estimates of projected recharge rates under the 2030 and 2070 climate change scenarios. This comment's suggestion to use historical recharge rates for projected water budgets does not constitute best available information and science and does not meet the requirements of a GSP outlined by 23-CCR §354.18.

LSCE Comments	Responses
27. The GSP states, "…these results suggest that projects and/or management actions may be required to consistently maintain water levels above MTs and to achieve MOs within the Marina-Ord Area unless SWI protective boundary conditions are achieved in the adjacent subbasins." (p. 6-51). **Comment:** The 180/400 Foot Aquifer Subbasin GSP is approved by DWR with the MO/MT included in the GSP. It is not reasonable to evaluate/assume boundary conditions could be at the apparently much higher "SWI protective boundary conditions". Thus, it should be assumed that projects/management actions will be required in Monterey Subbasin to maintain water levels above MTs and achieve MOs within the Marina-Ord Area.	See response to comment 16.
28. GSP Figure 6-8 indicates that Monterey Subbasin does not meet its MT when using MT boundary conditions for adjacent basins and does not meet its MO when using MO boundary conditions for adjacent basins in future project model runs for "No Project" conditions (p. 6-52). **Comment:** These results demonstrate that projects/management actions will be necessary to meet MT and MO in Monterey Subbasin. The GSP Project with water supply augmentation by recycled water of 5,500 AFY far exceeds any other current projections of available recycled water (less than 1,500 AFY in MCWD UWMP).	See response to Comments 16 and 19.
Section 6.6 (Historical, Current, and Projected Overdraft and Sustainable Yield)	
29. The GSP presents three methods of calculating sustainable yield of the Marina-Ord Area (p. 6-59 to 6-60). **Comment:** Two of the three methods are based on comparing historical and current overdraft to groundwater pumping during these time frames, with resulting sustainable yield ranging from 2,714 to 3,294 AFY, or an average of approximately 3,000 AFY. This estimate is likely reasonable given that historical and current pumping amounts ranging from 3,503 to 4,346 AFY have resulted in groundwater basin overdraft and seawater intrusion. The third method of calculating sustainable yield in the GSP erroneously concludes that the projected water budget results support an estimated sustainable yield of 9,870 AFY, which is three times the amount of groundwater pumping that has already resulted in overdraft and seawater intrusion. Furthermore, this sustainable yield estimate is on the order of 50% greater than total groundwater recharge. While the GSP claims a sustainable yield of up to 9,900 AFY, it is clear from historical and current data that the sustainable yield of the Marina-Ord Area is likely no greater than about 3,000 AFY.	It should be noted that on average -9,307 AFY of groundwater flowed inland from the Monterey subbasin into the 180/400 Foot Aquifer Subbasin in Water Year 2015-2018 where groundwater levels are well below sea level and lower than the Monterey Subbasin. The projected water budget analysis is also based on data inputs that best reflects future conditions, including climate change and boundary conditions assuming adjacent subbasin would achieve sustainability under SGMA.

LSCE Comments	Responses
30. The GSP states that under the "no project" scenario RMS well groundwater levels "…are generally higher than MTs during non-drought periods under all identified boundary conditions and climate scenarios…" and that RMS well groundwater levels "…reach MOs if SWI protective boundary conditions are achieved in adjacent subbasins." (p. 6-60). **Comment:** Review of Figure 6-7 indicates that groundwater levels are below the MTs more than 50% of the time after 2040 under MT boundary conditions, which is contrary to statements in the GSP. In addition, the DWR-approved 180/400 Foot Aquifer Subbasin GSP does not propose to achieve SWI protective groundwater levels; therefore, Monterey Subbasin RMS wells will not achieve proposed MOs.	See response to Comment 16.
31. The GSP states that the future projected sustainable yield ranges between 4,400 and 9,900 AFY if adjacent subbasins are managed sustainably and the 180/400 Foot Aquifer Subbasin reaches its SMCs (p. 6-60). **Comment:** While there is some interdependence between subbasins that may impact the sustainability of adjacent subbasins, each subbasin in the Salinas Valley needs to be managed sustainably on its own to make the entire Salinas Valley sustainable. The 180/400 Foot Aquifer Subbasin GSP has been approved by DWR as doing its part to achieve sustainability. Seaside Basin has been adjudicated and is doing its part to be sustainable. Monterey Subbasin cannot rely on inflows from other subbasins (e.g., from Seaside Basin) nor simply blame other subbasins (e.g., the 180/400 Foot Aquifer Subbasin) for its own inability to reach sustainability. The Monterey Subbasin should do its part to become sustainable by balancing its vertical inflows and outflows (i.e., do not include adjacent subbasin inflows and outflows), including a sufficient allowance for outflows to the ocean to avoid seawater intrusion. Alternatively, Monterey Subbasin GSAs may choose to work with the adjacent 180/400 Foot Aquifer Subbasin to develop other means of achieving sustainability such as by implementing a coordinated groundwater extraction barrier to address seawater intrusion.	Estimated groundwater recharge in the Monterey Subbasin is approximately 10,055 AFY, which far exceeds historical estimated rates of groundwater extraction (i.e., 5,274 AFY), yet the subbasin is in overdraft. If all subbasins were held to the criteria proposed by the author (i.e. simply by balancing its vertical inflows and outflows), the Monterey Subbasin would not be in overdraft and would not require that an extraction barrier be built.
32. The GSP states with regard to the projected sustainable yield range for the Marina-Ord Area of 4,400 to 9,900 AFY, that that ability to conduct this amount of pumping without inducing seawater intrusion needs to be verified (p. 6-60). **Comment:** It is not clear why pumping amounts in excess of historical pumping amounts that induced seawater intrusion would be proposed in a GSP without first verifying that they would not be expected to induce seawater intrusion. The groundwater model developed for the GSP should be applied to address this issue.	Seawater intrusion is the result of the combined effects of groundwater pumping within the greater Salinas Valley Groundwater Basin. As articulated in the GSP, a coordinated approach is required to reach sustainability in the Monterey Subbasin and other subbasins in the greater Salinas Valley Groundwater Basin.

LSCE Comments	Responses
Other General Comments	
33. The HWG previously reviewed Draft GSP Chapters 4 and 5 for the Monterey Subbasin, and provided comments dated April 5, 2021 (attached to this letter). While the HWG comments were acknowledged as being received by the GSA, the Public Draft versions of Chapters 4 and 5 include no significant changes to the text or figures related to the HWG comments. Furthermore, unlike responses provided to other comments submitted on the draft GSP chapters, there have been no responses to the HWG comments. Given that GSP development is a public process that is required include substantial public and stakeholder participation, and given that GSPs must be based on the best available science, the GSP should be revised to address the HWG's comments and the comments set forth herein. If the GSAs disagree with any of the subject comments, the GSAs should at the very least provide responses to the comments as they did for other comments.	Responses to these comments will be provided in the final draft of the GSP scheduled to be published on December 13, 2021.
33. Chapter 6 of the GSP makes several references to details of the groundwater model being described in Appendix 6B; however, Appendix 6B had not been provided for review as of October 29, 2021, and comments were due on November 1, 2021. Given that the entire Chapter 6 is essentially based on the groundwater model developed for the GSP, the GSAs' failure to provide this model documentation precludes stakeholders and the public from being able to adequately review and comment on a foundational element of the entire GSP. The GSP cannot undergo adequate review until a sufficient review period is provided for Appendix 6B Model Documentation, and additional time should be provided to comment on Appendix 6B once it is provided to the public.	Appendix 6B, which contains the model documentation, has been made available. It was uploaded to MCWD's website on 11/10/2021.

11/19/2021 – Comments on Monterey Subbasin Public Draft GSP Appendix 6B (Monterey Subbasin Groundwater Flow Model Documentation)

"This letter is submitted on behalf of California American Water and provides comments on Appendix 6B (Monterey Subbasin Groundwater Flow Model Documentation) for the Public Draft Monterey Subbasin GSP updated appendices released on November 10, 2021. Detailed comments are provided along with a summary of the main comments. Overall, given the number of significant deficiencies identified in these comments, the Monterey Subbasin groundwater model as currently configured does not provide reliable model results for use in GSP implementation."

SUMMARY OF COMMENTS

Although limited by the available time frame for review of Monterey Subbasin GSP Appendix 6B, many detailed comments are provided above. A few of the major takeaways from this review include the following:

- The HWG previously reviewed Draft GSP Chapters 4 and 5 for the Monterey Subbasin GSP and provided comments dated April 5, 2021. While the HWG comments were acknowledged as being received by the GSA, the Public Draft versions of Chapters 4 and 5 included no significant changes to the text or figures related to the HWG comments. Furthermore, these previous comments have direct bearing on the groundwater model development documented in Appendix 6B, and it is apparent that these previous HWG comments were not considered in Monterey Subbasin groundwater model development. In particular, the HCM in northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin is fatally flawed (in terms of model layering and boundary conditions) to the extent it will impact model results and lead to inaccurate future predictions of groundwater elevations and seawater intrusion in this area of the model domain.
- Although the allowed review time was insufficient to conduct a review of model calibration for Model Layers 3 through 7, review of calibration hydrographs and associated calibration statistics for Model Layers 1 (Dune Sand Aquifer) and 8 (Deep Aquifer) indicate model calibration is not within acceptable limits for the Marina Ord portion of the model domain.
- The historical challenges in achieving acceptable calibration for the Dune Sand Aquifer have not been resolved in the Monterey Subbasin groundwater model. The Kv for the underlying Model Layer 2 had to be set at unrealistically low values even to achieve the relatively poor calibration of Model Layer 1 documented in this comment letter. Utilizing a realistic Kv value for Model Layer 2 presumably would have resulted in an even worse model calibration for Model Layer 1.
- It is not clear why a No Flow boundary condition at the ocean shoreline would be used for the Deep Aquifer. This choice of boundary condition will likely lead to inaccurate future predictions of groundwater elevations and seawater intrusion.

LSCE Comments	Responses
Section 2 (Methodology and Approach)	
1. Appendix 6B states the model western boundary ends at the Pacific Ocean (section 2.2.1, p. 7). **Comment:** The Principal Aquifers (180-Foot Aquifer, 400-Foot Aquifer, Deep Aquifer) extend out beneath the ocean several miles beyond the Pacific Ocean shoreline. More representative model results would be obtained by extending the model domain further out beneath the ocean.	There is very limited data and information available regarding principal aquifer depths/geometry, aquifer properties, and historical water level observations to support extending the active model domain offshore of the Monterey coastline at this time. As described in Appendix 6B, general head boundary (GHB) cells were assigned along the coastline to simulate subsurface exchange with the Pacific Ocean. Freshwater equivalent sea levels were assigned to GHB cells based on estimated offshore distances and depths at which principal aquifers contacted the seafloor, which were informed by previous hydrogeologic investigations (*Feeney, 2003*).

LSCE Comments	Responses
2. Appendix 6B states the model is discretized vertically into eight layers that include Layer 3 representing the Upper 180-Foot Aquifer, Layer 4 representing the 180-Foot Aquitard, Layer 5 representing the Lower 180-Foot Aquifer (Section 2.2.3, p. 8). **Comment:** While this model layering may apply in the southern part of the Monterey Subbasin in the Fort Ord area, it does not apply in the northern Monterey Subbasin or the southern 180/400 Foot Aquifer Subbasin included in the model domain, where there is no aquitard within the 180-Foot Aquifer. This comment relates to the Hydrogeologic Conceptual Model (HCM) that forms the basis of the groundwater model and was noted in previous Hydrogeologic Working Group (HWG) comments on GSP Chapters 4 and 5 (April 5, 2021). This incorrect portrayal of the stratigraphy in the model layering in the northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin results in inaccurate model predictions in terms of groundwater levels and seawater intrusion.	See response to comments 7, 10, 11, and 15 of the HWG Chapter 4 comment letter (dated 04/05/2021). The MBGWFM <u>does</u> represent a gap in the 180-Foot Aquifer in the northwestern and central portions of the Monterey Subbasin and in the southwestern portion of the 180/400-Foot Aquifer Subbasin. In these areas, Layer 4 cells are assigned a thickness of 5 feet and parameterized using the aquifer properties from Layer 3 such that they function as "flow-through" cells and allow for hydraulic connectivity between Layers 3 and 5. This approach was used to avoid a no-flow condition in Layer 4 cells with zero thickness, as MODFLOW-NWT cannot directly simulate pinched out layers (see Section 2.2.3 of Appendix 6B for further details). However, we have noticed an error in Figure 6 that does not correctly show the "flow-through" portions of Layer 4 as described above. This error has been corrected and will be reflected in the final MBGWFM documentation. A screenshot of Layer 4 thickness is provided below, where "flow-through" cells are delineated in light grey: 
LSCE Comments	Responses
3. Appendix 6B states that as part of GSP development, a 3-D hydrostratigraphy model was developed to, "…provide for a more accurate representation of Principal Aquifer and Aquitard geometries and to facilitate MBGWFM grid development. The Leapfrog hydrostratigraphy model of the Basin was originally developed as part of two Airborne Electromagnetic (AEM) geophysical surveys conducted by Marina Coast Water District (MCWD) in 2017 and 2019…to help characterize seawater intrusion within the Basin." (Section 2.2.3, p. 9). **Comment:** Previous HWG Comment letters (e.g., August 2018, April 2019, June 2020) have repeatedly demonstrated the significant uncertainties and flaws in the hydrostratigraphic interpretations derived from the two AEM surveys. These errors in hydrostratigraphic interpretation have been incorporated into the Monterey Subbasin groundwater model and will result in inaccurate predictions of future groundwater levels and seawater intrusion. One example of the flawed stratigraphic interpretation for the northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin is provided in Figure 2 of Appendix 6B 2, which displays a thick and continuous aquitard in the middle of the 180-Foot Aquifer and no Aquitard between the 180-Foot Aquifer and 400-Foot Aquifer. These two aquitards are misrepresented (and essentially reversed) in this area of the model domain.	See response to comment 2 above.
4. Appendix 6B states, "…it is assumed the Deep Aquifer is not hydraulically connected to the Pacific Ocean." (Section 2.4.1, p. 12). **Comment:** The lack of seawater intrusion in the Deep Aquifer at the present time is insufficient basis for adopting a No Flow boundary in the groundwater model. It is possible the Deep Aquifer is connected to the Pacific Ocean at the Monterey submarine canyon. At the very least, the Deep Aquifer likely extends out beneath the ocean floor for many miles offshore.	Representation of the Pacific Coast as a no-flow boundary within the Deep Aquifer (Layer 8) is consistent with previous numerical models developed for the region, including the Seaside Model and SVIGSM. Boundary condition assumptions within the Deep Aquifer will be revisited in a future model update (e.g., for the seawater intrusion model currently under development) as more information becomes available.

LSCE Comments	Responses
5. Appendix 6B describes the historical groundwater level measurements used as input for the general head boundaries on the northern edge of the model domain as including, "…seven wells in the Upper 180-Foot Aquifer (Layer 3), 12 wells in the Lower 180/400-Foot Aquifer (Layers 5 and 7)…". There is a footnote associated with this text that reads, "MCWRA water levels records classify wells in a grouped "Lower 180/400-Foot Aquifer" system, and thus specified heads from these wells were assigned to both Layer 5 and Layer 7 of the MBGWFM." (Section 2.4.2.1.1, p. 12). **Comment:** This assignment of historical water levels to general head boundaries along the northern edge of the model domain is flawed for the reasons described above related to an inaccurate HCM stratigraphy. MCWRA maps of groundwater elevations clearly show distinct (different) groundwater elevations in the 180-Foot and 400-Foot Aquifers. The footnote relative to MCWRA category of wells in a "Lower 180/400-Foot Aquifer" system likely refers to wells screened in both aquifers and does not mean both aquifers have the same water levels as is assumed in the Monterey Subbasin groundwater model.	We recognize that MCWRA does not explicitly distinguish between the Upper 180-Foot and Lower 180-Foot Aquifers within most of the Salinas Valley Basin. However, within the Monterey Subbasin, the Upper 180-Foot Aquifer and Lower 180-Foot Aquifer are defined as distinct Principal Aquifer Units due to notable differences in water levels caused by the local presence of the 180-Foot Aquitard. Along most of the northern MBGWFM boundary, the 180-Foot Aquitard is present while the 180/400-Foot Aquitard is absent (see Figures 6 & 7 of Appendix 6B). Historical water level observations collected in this area indicate that groundwater elevations within the Lower 180-Foot Aquifer closely resemble water levels in the 400-Foot Aquifer along the northern basin boundary. Furthermore, water level contour maps for the Lower 180-Foot Aquifer created by EKI closely resemble MCWRA contour maps of the 400-Foot Aquifer along the boundary. As such, we chose to assign heads to GHB cells in MBGWFM Layers 5 and 7 using water levels collected from MCWRA wells characterized in the "180/400-Foot Aquifer." We agree there is considerable uncertainty in water level conditions within each Principal Aquifer unit along the northern MBGWFM boundary and have committed to coordinate with SVBGSA in revisiting northern boundary condition assumptions in a future model update as more information becomes available.
6. Appendix 6B states, "The final network of SGMA monitoring wells used for projected simulations includes seven wells in the Upper 180-Foot Aquifer (Layer 3), 10 wells in the Lower 180/400-Foot Aquifer (Layers 5 and 7)…" (Section 2.4.2.1.2, p. 13). **Comment:** This assignment of future water levels to general head boundaries along the northern edge of the model domain is flawed for the reasons described above related to an inaccurate HCM stratigraphy. MCWRA maps of groundwater elevations clearly show distinct (different) groundwater elevations in the 180-Foot and 400-Foot Aquifers.	See response to comments 2 and 5 above.

LSCE Comments	Responses
7. In describing the southern model domain boundary of the Monterey Subbasin groundwater model, Appendix 6B describes notable differences in "hydrogeologic conceptualization and geometry between the two models that will result in imperfect matching of head conditions and unique estimates of cross-boundary flows. Notably, the Seaside Model defines aquifer units differently than the MBGWGM and includes a different number of layers." (Section 2.4.2.2.1, p. 15). **Comment:** Although not described or acknowledged in Appendix 6B, this same issue of significantly different hydrogeologic conceptualization and geometry also applies along the northern model domain of the Monterey Subbasin groundwater model. This is due to the previously described flawed HCM and stratigraphy that served as the basis for model layering in northern Monterey Subbasin and southern 180/400-Foot Aquifer Subbasin.	See response to comments 2 and 5 above.
8. Appendix 6B Table 2 provides a comparison of Seaside Model Layers to MBGWFM Layers (Section 2.4.2.2.1, p. 16). **Comment:** A similar table showing the disagreement with the HCM and previous models of the 180/400-Foot Aquifer Subbasin are not provided. A table comparing the Monterey Subbasin groundwater model aquifer layers with the 180/400-Foot Aquifer Subbasin is provided below. This table shows the discontinuities and offset of aquifer units between the two subbasins, which is quite problematic for evaluation of groundwater levels and sea water intrusion between the two subbasins.	See response to comments 2 and 5 above.

Table from Comment 8:

Monterey Subbasin Aquifer Unit	180/400 Foot Aquifer Subbasin Aquifer Unit	Comments
Dune Sand Aquifer	Dune Sand Aquiferand Perched "A"Aquifer	The Dune Sand Aquifer is perched and mounded on top of SVA and cannot be readily represented in MODFLOW. Appendix6B does not explain how this unit was simulated.
Upper 180-Foot Aquifer	180-Foot Aquifer	The grouping of lower 180 and 400-Foot Aquifers in MBGWFM is inconsistent with all previous and existing models of the 180/400-Foot Aquifer Subbasin.
Lower 180-Foot Aquifer And 400-Foot Aquifer		
	400-Foot Aquifer	
Deep Aquifer	Deep Aquifer	

LSCE Comments	Responses
9. Appendix 6B describes how similar estimates of cross-boundary flows were obtained along the southern model domain boundary for both the Seaside Basin model and the Monterey Subbasin groundwater model (section 2.4.2.2.1, p. 16). **Comment:** Similar cross-boundary flows were not obtained across the northern model domain boundary compared to the 180/400-Foot Aquifer Subbasin GSP, which was approved by DWR.	See response to comment 6 of LSCE comment letter #1 (dated 11/1/2021)

LSCE Comments	Responses
10. Appendix 6B states, "Various studies and projects have been proposed (see GSP Section 9) or are already being implemented by water management entities in both subbasin to better characterize and model local groundwater conditions and cross-boundary flows in the Laguna Seca area and across the entire Monterey-Seaside boundary." (Section 2.4.2.2.2, p. 17). **Comment:** A similar statement regarding additional studies to address discrepancies in cross-boundary flows along the northern model domain boundary does not appear to be provided Appendix 6B or the remainder of the GSP.	Comment noted. A statement will be added to Appendix 6B.
11. Appendix 6B states, "More recent investigations of seawater intrusion conditions within the Basin…also indicate that the Deep Aquifer is not currently seawater intruded along the Monterey coastline. As such, GHB cells were assigned along the Pacific Ocean boundary for all layers in the MBGWFM apart from layer 8 (i.e., the Deep Aquifer), which was modeled as a no-flow boundary at the Monterey coastline.".'' (Section 2.4.2.3, p. 18). **Comment:** The Deep Aquifer is certain to extend many miles out beneath the ocean, possibly ultimately outcropping in the submarine Monterey Canyon. While it would be best to extend the model domain extent out beneath the ocean, the next best choice is to assign a general head boundary. The selected choice to assign a no-flow boundary to the Deep Aquifer is flawed and is likely to result in erroneous predictions of future groundwater levels and seawater intrusion.	See response to comments 1 and 4.
12. Appendix 6B describes texture maps based on borehole log lithologic descriptions for model layers 1, 3, 5, 7, and 8, which represent the various aquifers. (Section 2.5.1, p. 21). **Comment:** It is just as important (maybe more important) to develop such texture maps for the aquitard model layers 2, 4, and 6, but apparently this was not done or is not presently described.	Interval-based lithology data collected from borehole logs are generally insufficient in detail to assign spatial texture classifications to the aquitard units using the method described in Appendix 6B. Typically, aquitards are identified from borehole logs based on the presence of relatively consistent fine-grained deposits. Therefore, assigning a "coarse fraction" to aquitard units is impractical using the lithology interval data alone, as it will almost always result in a 0% coarse fraction throughout the entirety of the aquitard. Rather, the MBGWFM accounts for local variations in aquitard transmissivity by assigning unique thicknesses and extents to each aquitard layer at a cell level. Where gaps or missing sections of the aquitards are known to occur, these are represented in the MBGWFM using a "flow-through" cell approach to allow for direct exchange between overlying and underlying model layers. See response to comment 2 and Section 2.3.3. of Appendix 6B for further details.
Section 3 (Stresses)	

LSCE Comments	Responses
13. Appendix 6B states, "…it was assumed that 25% of total projected deliveries would be applied for outdoor uses between April – September, while the remainder of deliveries would be used to meet potable and non-potable indoor demands." (Section 3.1.2.3, p. 27). **Comment:** While this assumption seems reasonable, it is inconsistent with the primary proposed future project of meeting 50% of future water demands with recycled water (see Table 8 on page 28 of Appendix 6B), which would require extensive indoor use of recycled water.	The author is correct. Recycled water would be used to meet indoor as well as outdoor demands. This would be accomplished through IPR (injection of recycled water into the aquifer) as described in in GSP Section 9.4.6 (project M3) cited in Appendix 6B, Section 3.2.2
14. Appendix 6B states, "For both scenarios, pumping was distributed within individual MCWD wells based on historical monthly and total pumping rates at each well." (Section 3.2.2, p. 28). **Comment:** As noted in the GSP Chapter 6 comment letter submitted on November 1, 2021, future pumping of MCWD wells based on historical pumping patterns does not accurately reflect pumping trends towards a greater amount of pumping from the Deep Aquifer.	See response to comment 15 of LSCE comment letter #1 (dated 11/1/2021).
15. Appendix 6B Table 8 (Projected MCWD Pumping Rates) shows total water demand in 2040 of 9,584 AFY with 5,495 AFY provided by recycled water and 4,089 of actual groundwater pumping. In addition, water demand is projected to increase from 3,367 AFY in 2020 to 6,001 AFY in 2025, with the vast majority of that increase being covered by increased groundwater pumping (Section 3.2.2, p. 28). **Comment:** It is not clear how recycled water can realistically provide 57% of total water demand in 2040. Near term, an increase in groundwater pumping from 3,367 AFY to 5,401 AFY in 2025 is likely to exacerbate seawater intrusion that is already occurring with 3,367 AFY of groundwater pumping by MCWD.	See response to Comment 13. Groundwater monitoring will be used to verify that SMCs are met.
Section 4 (Calibration)	

LSCE Comments	Responses
16. Appendix 6B states that the discrepancy in cross boundary groundwater flow estimates between the Monterey Subbasin GSP and 180/400 Foot Aquifer Subbasin GSP is due to 180/400 Foot Aquifer Subbasin GSP estimates being made by non-modeling methods, and that the 180/400 Foot Aquifer Subbasin GSAs plan to do additional studies of cross-boundary flows for the 5-Year Update. It is noted that the estimates in the 180/400 Foot Aquifer Subbasin were derived from, "…aggregating data and analyses from previous reports and other available sources. No numerical modeling was completed to develop the historical or current water budget." (Section 4.4, p. 31). **Comment:** The implication of the Appendix 6B text is that the non-modeling methods of determining water budgets and cross- boundary flows must be wrong. However, water budgets are commonly done using non-modeling methods, even if ultimately being used as input to a numerical model from which the final water budget is determined. For example, the 180/400 Foot Aquifer Subbasin describes using stream gage data at multiple stations to determine streamflow percolation, which likely is better than a model estimate. Furthermore, the historical and current estimates of groundwater inflow/outflow for the 180/400 Foot Aquifer Subbasin are based in part on the Salinas Valley IGSM groundwater model. In addition, the 180/400 Foot Aquifer Subbasin GSP notes that future water budgets were based on the SVIHM groundwater model developed by USGS. Overall, both subbasins estimated groundwater inflow/outflow amounts using groundwater models.	See response to comment 6 of LSCE comment letter #1 (dated 11/1/2021).
17. Appendix 6B states that, "SVIHM does not accurately reflect hydrologic conditions in the Monterey Subbasin." (Section 4.4, p. 31). **Comment:** This statement is used to help justify Monterey Subbasin GSP cross-boundary groundwater flow estimates being more reliable than those provided in the 180/400 Foot Aquifer Subbasin GSP. However, as noted above in this comment letter and in the previous HWG comment letter on Monterey Subbasin GSP Chapters 4 and 5, the HCM used as the basis for the Monterey Subbasin groundwater model is flawed in the northern Monterey Subbasin and southern 180/400 Foot Aquifer Subbasin portions of the model domain and does not accurately reflect geologic or hydrologic conditions along the northern Monterey Subbasin groundwater model domain boundary. Thus, the basis for Monterey Subbasin GSP estimates for cross-boundary flows are likely less valid than those provided in the 180/400 Foot Aquifer Subbasin GSP that has already been approved by DWR.	See response to comments 2 and 5 above, and comment 6 of LSCE comment letter #1 (dated 11/1/2021).

LSCE Comments	Responses
18. Appendix 6B states, "SVBGSA is in the process of developing a dual density groundwater model for the coastal regions of the greater Salinas Valley Basin. This model will incorporate the MBGWFM and be used to further assess volumetric exchanges between the ocean and the Salinas Valley groundwater basin. It will also aid in evaluating flows across subbasin boundaries and will be used evaluate impacts of potential regional projects that have been proposed in this GSP and other GSPs to address seawater intrusion in the Salinas Valley groundwater basin." (Section 4.4, p. 31). **Comment:** Given that the MBGWFM is expected to be expanded and have uses much greater than and beyond the scope of the Monterey Subbasin GSP, it is critical that the hydrostratigraphic misrepresentation and flawed model layering (and model boundary conditions) outlined above be addressed for this broader effort (and preferably for use in the Monterey Subbasin GSP itself).	See response to comments 2 and 5 above, and comment 6 of LSCE comment letter #1 (dated 11/1/2021).

LSCE Comments	Responses
19. Appendix 6B Table 10 indicates the Normalized RMSE for Model Layer 1 is 5.7% based on a range in elevations of 198.4 feet; and that the Normalized RMSE for Model Layer 8 is 2.9% based on a range in elevations of 728.4 feet. The text states, "A generalized rule of thumb in model calibration is that the model is considered well-calibrated when the normalized RMSE is less than 10%. The low normalized RMSEs are therefore an indicator that the model is well-calibrated as a whole and within individual layers given the range of observed data." (Section 4.7, p. 33). **Comment:** Review of the hydrographs indicates the range in elevations for Model Layer 1 is not more than 115 feet, resulting in a Normalized RMSE of about 10%. Even if there were an outlier somewhere in the hundreds of hydrographs provided, it would be an extreme outlier that artificially increased the range of elevations and lowered the RMSE to 5.7 %. Overall review of hydrographs indicates the calibration of the Dune Sand Aquifer is not particularly good and is no better than previous models of the area. The extreme range in elevations of 728.4 feet for Layer 8 is apparently mixing data from near the ocean in the Marina-Ord area with the highest elevations of the Corral de Tierra area, which artificially lowers the Normalized RMSE by a large amount. A more realistic groundwater elevation range of about 95 feet for the Marina Ord area for which hydrographs show an RMSE of about 14.5 feet yields a Normalized RMSE of about 15%. There was insufficient time to do similar checks on other model layers, but results for Model Layers 1 and 8 indicate a relatively poor overall calibration for the Marina-Ord area. It is also noted that while the Monterey Subbasin modeling effort appeared to use practically all available monitoring well data for model calibration (with notable exception of MPWSP data); however, the monitoring well hydrograph for MW-OU2-29-A is missing from the dataset for the Dune Sand Aquifer, which is noteworthy because it was a particularly challenging hydrograph to match with previous models.	This comment appears to make a generalized statement about MBGWFM calibration by focusing on a subset of wells and layers within a local area of the model domain that is of particular interest to CalAm. There is no actionable recommendation provided in the comment. As mentioned in previous replies, the focus of MBGWFM is to provide a reasonably calibrated, Basin-level model of the Monterey Subbasin that serves as a starting point for coordinated regional model development and/or refinements. Appendix 6B demonstrates that model calibration, both within individual layers and as a whole, falls within acceptable performance criteria and reasonably recreates Basin-level groundwater conditions. Model performance within CalAm's area of interest in the Basin was not a primary focus of MBGWFM development or calibration.
20. Appendix 6B provides a map (Figure 29) of calibration hydrograph locations (Section 4.7, p. 33). **Comment:** It is not clear why nested monitoring well data from the Monterey Peninsula Water Management Project (MPWSP) are not being used in the model calibration. These wells are located in key data gap areas of the model domain.	MPWSP monitoring wells were installed in 2015. Therefore, data from these wells begins in year 18 of the 20 year historical calibration period which extends from (WY 1999 through WY 2018). As such, they were not selected for incorporation into the calibration data set for the historical period. However, data from these wells will be incorporated into future model updates that focus on future time periods.
Section 5 (Sensitivity and Uncertainty Analysis)	

LSCE Comments	Responses
21. Appendix 6B states the final calibrated Kv of Model Layer 2 was 2 x 10-4 ft/d (Section 5, p. 34). **Comment:** A Kv of 2 x 10-4 ft/d is equivalent to 7 x 10-8 cm/s. This is an extremely low and unrealistic Kv value for a regional clay layer. Such an unrealistically low calibrated Kv value was likely driven by trying to achieve a better calibration within the overlying Model Layer 1. Previous studies indicate that accurately representing (from a hydrogeologic standpoint) the Dune Sand Aquifer (Model Layer 1) is extremely difficult because it contains perched and mounded water on top of a sloping clay layer and numerical models have trouble accurately representing such hydrogeologic conditions. The text of Appendix 6B provides no discussion of this issue and how it was addressed in the Monterey Subbasin groundwater model. The consultants that prepared Appendix 6B are quite familiar with the issue and have critiqued previous models in the area regarding this issue, yet they provide no explanation of how the issue was addressed in their own model. Regardless, it is clear from detailed inspection of calibration hydrographs for Model Layer 1 and the use of an unrealistically low Kv value for Model Layer 2 that these model challenges for simulating the Dune Sand Aquifer remain unresolved for the Monterey Subbasin groundwater model.	A Kv value of 2E-4 ft/d is well within the range of hydraulic conductivity values for clay layers presented in relevant literature, and in most cases, represents the upper limit of the range. For example, *Freeze and Cherry, 1979* presents a range in hydraulic conductivity of 8E-13 m/s (2E-7 ft/d) to 2E-9 m/s (6E-4 ft/d) for unweathered marine clays. For silt/loess, the range is higher, from 1E-9 m/s (2E-4 ft/d) to 2E-5 m/s (5.7 ft/d). Furthermore, the calibration metrics presented in Appendix 6B indicate the model is reasonably well calibrated in Layer 1, with RMSE of 11.5 ft (5.7%) and a mean residual of -0.4 ft. The model was set up with the properties of the Dune Sand and underlying Salinas valley aquitard (SVA) in mind. As indicated above, the SVA model layer 2 was parameterized to reflect the low permeability associated with marine layer deposits. The model is also set up to be fully convertible in each layer to allow representation of varying degrees of confinement and saturation within each aquifer unit. It also allows for rewetting to accommodate situations where certain layers and/or cells go dry during the simulation.
Section 6 (Model Limitations and Suggested Future Refinements)	
22. Appendix 6B states, "…the model calibration error is within acceptable bounds…As demonstrated by the calibration error statistics summarized in Section 4.7 the MBGWFM reasonably represents historical groundwater conditions within the Subbasin using a set of parameters that are within real- world observations and established scientific principles." (Section 6, p. 35). **Comment:** As discussed previously: 1) A limited review of the calibration data indicates Model Layers 1 and 8 are poorly calibrated (time did not permit for checking calibration of other model layers); 2) the HCM forming the basis for model layering and general head boundary conditions on the northern portion of the model domain are flawed; and 3) the calibrated Kv for Model Layer 2 is unrealistically low by at least two orders of magnitude. These findings indicate the statements in Section 6 about model calibration being acceptable and the model being based on realistic model parameters are inaccurate.	See responses to comments 2, 5, 19, and 21 above.

LSCE Comments	Responses
23. Appendix 6B notes that, "…only a small number of wells exist in the Deep Aquifers within the 180/400 Foot Aquifer Subbasin with observed water level data spanning the full duration of the historical Period. As such, simulated Deep Aquifers heads along the northern model boundary are subject to the limitations in available data to the north of the boundary, which may impact resulting calculations of 180/400 Foot Aquifer Subbasin exchanges within the water budget." (Section 6, p. 35). **Comment:** It should be noted that the same limitations on available data are equally applicable south of the boundary.	Comment noted.
24. Appendix 6B notes that there is a lack of water level calibration data outside of certain areas such as the MCWD service area and former Fort Ord Site (Section 6, p. 36). **Comment:** While this statement is generally correct, there is no explanation as to why an extensive monitoring well data set for the MPWSP is not used in the model calibration – particularly given it is located in a data gap area.	See response to comment 20 above.
25. Appendix 6B notes there is significant uncertainty with the climate change predictions provided by DWR that are the basis for future scenarios in the GSP (Section 6, p. 37). **Comment:** Given the uncertainty in climate change predictions related to precipitation, it would be more prudent for future water management to assume that groundwater recharge will not increase in the future due to climate change (as has been assumed in the GSP) and assume instead it will remain consistent with historical data.	See response to comment 26 of LSCE comment letter #1 (dated 11/1/2021).

LANDWATCH COMMENTS ON DRAFT MONTEREY SUBBASIN GROUNDWATER SUSTAINABILITY PLAN, CHAPTER 8

"I write on behalf of LandWatch Monterey County to comment on draft Chapter 8 of the Monterey Subbasin Groundwater Sustainability Plan (GSP).

The sustainable management criteria (SMCs), including the minimum threshold (MT) and measurable objective (MO) for chronic lowering of groundwater levels for the Monterey Subbasin may suffer from the same defect as in the 180/400-Foot Aquifer

Subbasin Groundwater Sustainability Plan. That defect is that the groundwater level SMCs are not supported by consideration of their effects on other sustainability indicators, in particular, seawater intrusion. There appears to be no evidence that the groundwater level SMCs and their associated interim milestones will support attainment of the seawater intrusion threshold, particularly since the interim milestone would permit continued declines in historic groundwater levels and would not reach the SMCs for almost 20 years.

Furthermore, setting Corral de Tierra subarea groundwater level SMCs at historic levels would cause chronic lowering of groundwater levels in the neighboring Seaside Subbasin. According to the Seaside Basin Watermaster, pumping reductions and groundwater level increases are required in the Corral de Tierra subarea to remedy falling groundwater levels in the Laguna Seca Subarea.

Finally, the water quality sustainable management criteria should not be limited to effects caused by "direct GSA action" through GSA projects. The GSA must also limit excessive third party extractions that cause undesirable water quality results."

LandWatch Comments	Responses
Chapter 8 – Hydrogeologic Conceptual Model	
A. Groundwater level sustainable management criteria and interim milestones fail to support the seawater intrusion criteria.	
1. The groundwater level minimum threshold must support the seawater intrusion minimum threshold. SGMA requires that each minimum threshold must avoid each undesirable result because SGMA requires that "basin conditions at each minimum threshold will avoid undesirable results for each of the sustainability indicators." (23 CCR § 354.28(b)(2), emphasis added.) For example, the groundwater level minimum threshold must be "supported by" the "[p]otential effects on other sustainability indicators." (23 CCR 354.28(c)(1)(B), emphasis added.) This means that each minimum threshold, especially the groundwater level minimum threshold, must be coordinated to ensure that all undesirable results are avoided.	The Monterey Subbasin GSP contains groundwater level minimum thresholds that support the seawater intrusion minimum thresholds. As described in Landwatch comment number 4 below. Chap. 8, p. 8-29 states: The observed lateral extent of seawater intrusion within the Subbasin appears to have been generally stable within the 180- and 400-Foot Aquifers between 1995 and 2015. As such, minimum thresholds have been set based upon minimum groundwater elevations observed between 1995 and 2015 in the 180- and 400 Foot aquifers. Seawater intrusion is additionally monitored and managed pursuant to seawater intrusion SMCs (Section 8.9 below) to verify seawater intrusion does expand within the Subbasin due to sea-level rise and/or changes in the groundwater gradient. (Chap. 8, p. 8-29.)

LandWatch Comments	Responses
	As stated by LandWatch ("LW") in Comments 2, 3, and 4 the Monterey GSP calls for no further seawater intrusion and identifies sustainable management criteria based upon historical conditions to meet this measurable objective. Although the GSP allows for interim declines in water levels in the 400-foot aquifer in inland portions of the subbasin, it does not allow declines in wells located along the known seawater intrusion front within the northern portion of the subbasin (see response to LW comment 5). It also calls for installation of additional wells in the southern portion of the subbasin to better track water levels and seawater intrusion in this portion of the subbasin. This new data will be used to identify appropriate SMCs and interim milestones for groundwater levels in this area. Annual induction logging is also proposed to assess vertical migration of the seawater intrusion front between the 400-foot aquifer and the Deep Aquifers, where no seawater intrusion has been detected to date. These data will be reviewed, and interim milestones will be adjusted if needed. MCWD has significant flexibility to change extraction rates between in its production wells and increase water levels in selected areas in the event that seawater intrusion is identified. Annual and 5-year reports required under SGMA will be used to identify changes to water level SMCs and interim milestones if required. The interim milestones included in the Monterey GSP reflect the reality that it will take time to implement projects and management actions to stop groundwater levels from falling. As discussed in the GSP, rates of groundwater extraction within the Monterey Subbasin are significantly lower than total recharge, and large volumes of groundwater are flowing into the 180/400 foot groundwater basin. As such, sustainability with the Monterey Subbasin will require the implementation of both local and regional projects and management actions to reach sustainability. Such regional solutions will inevitably take time to implement. The Monterey GSP is consistent with SGMA, which acknowledges this reality and allows 20 years to reach sustainability. Further, in the event that such monitoring indicates expansion of the seawater intrusion

LandWatch Comments	Responses
	front, prior to reaching SMCs local projects such as IPR could be implemented to raise water levels in selected areas through injection of recycled water (i.e., IPR project) or in lieu recharge as identified in Chapter 9 . In the event that monitoring data indicate rapid vertical downward migration of the seawater intrusion front, interim water level SMCs may be adjusted to address this issue. Annual and 5 year reports required under SGMA will be used to identify such changes if required.
2. The proposed seawater intrusion SMCs do not permit any additional intrusion. The draft Monterey Subbasin Chapter 8 sets the MT and MO for seawater intrusion for the "lower" 180-Foot Aquifer and the 400-Foot Aquifer at the line of advancement as of 2015. (Monterey Subbasin GSP, draft Chap. 8 ("Chap. 8."), p. 8-55 to 8-56.) Chapter 8 sets the MT and MO for seawater intrusion to the Deep Aquifers at Highway 1, based on the observation that there is limited intrusion in these aquifers. (Id., pp. 8-51, 8-55 to 856.) In effect, Chapter 8 commits the GSP not to permit any additional seawater intrusion in these aquifers. This is a proper goal in light of the clear impacts to beneficial users.	As stated in LW Comment 2, the proposed seawater intrusion SMCs identified in Chapter do not permit any expansion of the seawater front.
3. The groundwater level SMCs and groundwater level interim milestones are set based on their effects on seawater intrusion. The draft Monterey Subbasin Chapter 8 acknowledges that the MT and MO for groundwater levels must support attainment of the seawater intrusion MT and MO because it identifies the primary consideration in setting the groundwater level MT and MO is the effect on seawater intrusion: As discussed in Section 3.1.6, groundwater use within the Marina-Ord Area is almost exclusively limited to generation of municipal supplies by MCWD. Groundwater elevations are significantly higher than municipal production well screen elevations in all aquifers in the Marina-Ord Area, and there is limited concern regarding the potential dewatering of groundwater production wells. Therefore, groundwater levels that could cause undesirable results associated with other locally relevant sustainability indicators, such as the lateral or vertical expansion of the existing seawater intrusion extent and/or eventual migration of saline	As stated in LW Comment 3, the intent of Chapter 8 is to establish MTs and MOs for groundwater levels that support attainment of the seawater intrusion MTs and MOs.

LandWatch Comments	Responses
water into Deep Aquifer wells, have been used to define groundwater level minimum thresholds in the Marina-Ord Area. (Chap. 8, p. 8-16, emphasis added.) Chapter 8 also provides that . . . undesirable results caused by chronic lowering of groundwater levels in the Marina-Ord Area are primarily associated with the expansion of seawater intrusion and other locally relevant sustainability indicators. These sustainability indicators have been considered when defining groundwater level minimum thresholds in the Marina-Ord Area. (Chap. 8, p. 8-18, emphasis added.)	
4. Setting the groundwater level SMCs at historic 1995-2015 conditions is purportedly justified by the stability of the lateral extent of seawater intrusion in the Monterey Subbasin during that historic period. Chapter 8 contends that setting the groundwater level MT and MO for the 180- and 400Foot Aquifers on the basis of the 1995 to 2015 groundwater levels is justified because the lateral extent of seawater intrusion in the Monterey Subbasin has been "generally stable" in that period: As discussed in the preceding sections, the potential effects of undesirable results caused by chronic lowering of groundwater levels in the Marina-Ord Area are primarily associated with the expansion of seawater intrusion. The observed lateral extent of seawater intrusion within the Subbasin appears to have been generally stable within the 180- and 400-Foot Aquifers between 1995 and 2015. As such, minimum thresholds have been set based upon minimum groundwater elevations observed between 1995 and 2015 in the 180- and 400 Foot aquifers.. Seawater intrusion is additionally monitored and managed pursuant to seawater intrusion SMCs (Section 8.9 below) to verify seawater intrusion does expand within the Subbasin due to sea-level rise and/or changes in the groundwater gradient. (Chap. 8, p. 8-29.)	As stated in LW comment 4, and GSP chapter 8 "available data indicate that the lateral extent of seawater intrusion front in the 180/400 Foot Aquifer in Monterey Subbasin has been stable between 1995 and 2015. As such, minimum thresholds have been set based upon minimum groundwater elevations observed between 1995 and 2015 in the 180- and 400 Foot aquifers. Seawater intrusion is additionally monitored and managed pursuant to seawater intrusion SMCs (Section 8.9 below) to verify seawater intrusion does expand within the Subbasin due to sea-level rise and/or changes in the groundwater gradient."
5. The "stability" rationale for setting groundwater level SMC's based on historic conditions is undercut by Chapter 8's projections that groundwater levels will	In order to limit migration of the seawater intrusion front; MT, MO, and <u>interim milestones</u> in 180/400 Foot aquifer RMWs located near the

LandWatch Comments	Responses
actually continue to decline and remain below historic conditions and by the interim milestones that permit such declines. First, the contention that groundwater level SMCs are justified by historic conditions ignores the GSP's own projection that groundwater levels will continue to decline until at least 2033 and will not attain the MO until 2042. Chapter 8 documents and projects in its "Example Trajectory for Groundwater Elevation Interim Milestones" that groundwater levels for a Marina-Ord well fell below the MT in 2019, will continue to fall until 2033, will not rise above the MT until 2039, and will not attain the MO until 2042. (Chap. 8, pp. 8-40 to 8-41, Figure 8-12.) The interim milestones for wells in the 400-Foot Aquifer and the Deep Aquifers assume and permit that groundwater levels will remain below historic levels and the MT for most of the next 20 years: Within the Monterey Subbasin, for wells in the 400-Foot Aquifer, Deep, and El Toro Primary Aquifer System Aquifers where groundwater levels have been declining, groundwater elevation interim milestones are defined based on a trajectory informed by current (fourth quarter of 2020) groundwater levels, historical groundwater elevation trends [footnote], and measurable objectives. This trajectory allows for and assumes a continuation of historical groundwater elevation trends during the first 5-year period of GSP implementation, a deviation from that trend over the second 5-year period, and a recovery towards the measurable objectives in the third and fourth (last) 5- year period. (Chap. 8, p. 8-40.) The proposed interim milestones for wells in the 180-Foot and Deep Aquifers permit substantial declines in groundwater levels from 2020 conditions in the years 2027 and 2032. (Id., p. 8-43, Table 8-3.) Allowing groundwater levels to fall below historic levels is purportedly justified because "there are large volumes of freshwater in the Subbasin that provide additional time and flexibility to reach identified SMCs while projects and management actions are implemented." (Id.) However, the draft GSP provides no evidence to suggest that groundwater levels that fall and remain below the historic conditions in the Marina-Ord area will not induce further seawater intrusion in the interim,	seawater intrusion front have all been set at minimum groundwater elevations observed between 1995 and 2015. These RMWs include: MCWD-29, 30, and 31, MPWMD#FO-10S and 11S, MW-12-12-180L, MW-BW-04-180, MW-OU2-07-400, MW-OU2-66-180, TEST2, and two multi-completion wells (MP-BW-42* and MP-BW-50*). No interim water level decreases in these wells are incorporated in the interim milestones for these RMWs. Nor is any interim decrease in water levels included in the proposed interim milestones for Dune Sand RMWs near the coast, where seawater intrusion is most likely to occur. Interim declines in water levels have been incorporated into SMCs for inland 400-foot wells and Deep Aquifer Zone wells, where no seawater intrusion has been observed to date. As such, proposed declines in interim milestones at these locations are not inconsistent with Seawater SMCs. The need for additional wells and monitoring to further assess the potential for lateral and vertical migration of seawater are proposed in Section 7.5.2 of the GSP: This work includes: 1. The completion of an additional 400-foot aquifer monitoring well in the southern portion of the Monterey Subbasin between the coast and wells FO-10 and FO-11, where water levels are falling. This well will be used to further evaluate the extent of if seawater intrusion in this area and evaluate groundwater levels. SMCs in this additional RMW will be established accordingly. 2. Annual induction logging at Deep Aquifer monitoring wells to assess potential vertical migration of seawater from the 400 Foot Aquifer into the Deep Aquifer. Data from these additional investigations will be utilized to inform future annual and 5-year reports to the GSP. If needed, groundwater level interim milestones and/or SMCs may be modified to achieve the Seawater intrusion SMCs.

LandWatch Comments	Responses
resulting in a failure to meet the seawater intrusion SMCs. The historic "stability" rationale cannot be extrapolated to claim that groundwater levels well below the historic record will continue to result in a stable areal extent of seawater intrusion. It makes no sense to contend that setting the MT and MO on the basis of historic conditions will not result in seawater intrusion when the GSP would effectively fail to maintain those historic conditions for the next twenty years during which the GSP is supposed to attain sustainability. The historic stability rationale also ignores the fact that Deep Aquifer groundwater levels began dropping in 2014, have continued to drop, and are projected to continue to drop due to increased levels of extractions. MCWRA reported in 2020 that Deep Aquifer groundwater levels have been falling since 2014, are well below sea-level, and that induced vertical migration of contaminated water to the Deep Aquifers themselves is in fact occurring: As is the case with the 180-Foot and 400-Foot Aquifers, groundwater levels in the Deep Aquifers are predominantly below sea level. Beginning around 2014, groundwater levels in the Deep Aquifers began declining and are presently at a deeper elevation than groundwater levels in the overlying 400-Foot Aquifer based on comparisons of multiple well sets at selected locations, meaning that there is a downward hydraulic gradient between the impaired 400-Foot Aquifer and the Deep Aquifers (Figure 16 and Figure 17). This decrease in groundwater levels coincides with a noticeable increase in groundwater extractions from the Deep Aquifers (Figure 16 and Figure 17). The potential for inducing additional leakage from overlying impaired aquifers is a legitimate concern documented by previous studies and is something that would be facilitated by the downward hydraulic gradient that has been observed between the 400-Foot Aquifer and Deep Aquifers. Seawater intrusion has not been observed in the Deep Aquifers. However, the Agency has documented the case of one well, screened in the Deep Aquifers, that is enabling vertical migration of impaired groundwater into the Deep Aquifers. The	

LandWatch Comments	Responses
Agency is working with the well owner on destruction of this well.[12] In addition to the threat to contaminate the Deep Aquifers, the induced vertical migration of upper aquifer groundwater to the Deep Aquifers aggravates seawater intrusion in those upper aquifers. A 2003 study for MCWD concluded that increasing pumping of the Deep Aquifers from the 2002 baseline level of 2,400 AFY to just 4,000 AFY would (1) induce further seawater intrusion into the upper aquifers (the 180-Foot and 400-Foot Aquifers), which were vertically connected, and (2) risk contamination of the Deep Aquifers themselves.[3] Deep Aquifer pumping is now in excess of 10,000 AFY.[4] And, in fact, Chap 8 admits that falling groundwater levels in the Deep Aquifer threatens to contaminate the Deep Aquifers and to induce seawater intrusion in the upper aquifers: Seawater intrusion has not been observed in the Deep Aquifer to date. However, groundwater elevations have been declining and are significantly below sea level. The declining groundwater elevations in the Deep Aquifer may be causing groundwater elevations to fall within the 400-Foot Aquifer in the southwestern portion of the Marina-Ord Area (i.e., near wells MPMWD#FO-10S and MPMWD#FO-11S). Although there is some uncertainty whether the Deep Aquifer is subject to seawater intrusion from the ocean, continued decline of groundwater elevations in the Deep Aquifers could increase the risk of seawater intrusion and may eventually cause vertical migration of saline water from overlying aquifers into the Deep Aquifers. As such, minimum thresholds for the Deep Aquifers are set to historically observed minimum groundwater

LandWatch Comments	Responses
elevations between 1995 and 2015, which is equivalent to the groundwater elevations observed in 2015 for most Deep Aquifer wells. (Chap. 8, p. 8-40.) Again, setting the groundwater level MT and MO to historic levels but then allowing 20 years to pass before the interim milestones actually require attainment of these historic levels cannot demonstrably ensure that there is no further advancement of seawater intrusion. However, that is precisely what is required by the seawater intrusion MT and MO.	
6. Chapter 8 fails to assess the effects on other subbasins of setting groundwater level SMCs based on historic conditions or allowing groundwater levels to decline further through relaxed interim milestones. As Chapter 8 acknowledges, the interconnectivity between the 180/400-Foot Aquifer Subbasin and the Monterey Subbasin requires coordination of the sustainable management criteria for both subbasins. (Id., p. 8-35.) Coordination is required in order to meet SGMA's requirement that the SMC's for one subbasin do not prevent another subbasin from meeting its sustainability goal. Setting the groundwater level MT and MO at historic levels and then effectively ignoring these criteria through use of relaxed interim guidelines for 20 years may very well impair attainment of the seawater intrusion criteria for the 180/400-Foot Aquifer GSP, which are also set at a level that permits no further advancement of the seawater intrusion front. However Chapter 8 provides no analysis of that possibility. Chapter 8 proposes to defer the assessment of the impact of the Monterey Subbasin's groundwater level MTs on the Deep Aquifers in the neighboring 180400-foot Aquifer Subbasin until after completion of the long-delayed Deep Aquifers Study and the eventual establishment of Deep Aquifer SMCs for the 180400-foot Aquifer Subbasin. The Deep Aquifer Study, recommended almost four years ago, has neither been funded nor initiated. Furthermore, there is no reason that an assessment of the effects of the Monterey Subbasin's groundwater level MTs should be limited to its effects on the Deep Aquifers in the 180/400-Foot Subbasin. The assessment should also include an assessment of the effects of the	As discussed in the GSP, rates of groundwater extraction within the Monterey Subbasin are significantly lower than total recharge, and large volumes of groundwater are flowing into the 180/400-foot groundwater basin. As such, sustainability with the Monterey Subbasin will require the implementation of both local and regional projects and management actions to reach sustainability. Such regional solutions will inevitably take time to implement and will require coordination with adjacent subbasins and of SMCs. The Monterey GSP is consistent with SGMA, which acknowledges this reality and allows 20 years to reach sustainability.

LandWatch Comments	Responses
Monterey Subbasin's groundwater level MTs on seawater intrusion of each of the principle aquifers in that neighboring subbasin. The Monterey Subbasin GSP argues that pumping in the 180/400-Foot Aquifer Subbasin has caused seawater intrusion in the Monterey Subbasin. In turn, the Monterey Subbasin GSP must assess the reciprocal effects of its own pumping, SMCs, and interim milestones on the 180/400-Foot Aquifer Subbasin. SGMA's mandate to use the best available science is not an invitation to let the perfect be an enemy of the good pending completion of the Deep Aquifer study. Chapter 8 must use the whatever science is now available to provide some discussion and assessment of the effect on the neighboring subbasins of allowing continued reductions in Monterey Subbasin groundwater levels below historic conditions through relaxed interim thresholds. Again, it is not reasonable to extrapolate beyond the historic data to assume that lower than-historic groundwater levels in the Monterey Subbasin will not impair adjacent basins. The purported stability of the lateral extent of seawater intrusion in the Monterey Subbasin from 1995 to 2015 was certainly not matched in the 180/400-Foot Aquifer Subbasin. Chapter 8 provides no evidence to justify the assumption that allowing lowerthan-historic groundwater levels in the Monterey Subbasin will not contribute to the continuing seawater intrusion in the neighboring subbasin.	
7. Finally, the Monterey Subbasin GSP must also evaluate and address the effects of reduced groundwater levels in the Corral de Tierra Subarea on the Seaside Subasin. Again, there is no evidence in the record that merely maintaining historic groundwater levels is sufficient to support groundwater levels in the Seaside Subbasin. To the contrary, comments by the Seaside Basin Watermaster indicate that chronic lowering of groundwater levels in the Laguna Seca Subarea of the Seaside Subbasin can only be corrected by reducing existing pumping in the Corral de Tierra, i.e., increasing groundwater levels above historic levels. (Robert Jacques, PE, email to Sarah Hardgrave, et al., March 22, 2021.) Setting Monterey Subbasin groundwater level SMC's at historic levels violates SGMA because it will prevent attainment of groundwater level objectives in the adjacent Seaside Subbasin.	SVBGSA and the Seaside Watermaster are in close coordination to monitor, model, and discuss water levels in the Corral de Tierra area for SMC and GSP development. While the hydrologic connection is clear, the future impacts as predicted by modeling are less clear. Modeling teams are in close contact to resolve discrepancies and develop improved predictions that meet the needs of all stakeholders.

LandWatch Comments	Responses
B. Water quality sustainable management criteria should not be limited to effects caused by "direct GSA action;" the GSP must also limit extractions that cause undesirable results.	
Chapter 8 purports to limit significant and unreasonable conditions related to groundwater quality degradation to "[l]ocally defined significant and unreasonable changes in groundwater quality resulting from direct GSA action." (Chap. 8, p. 8-56, italics added.) Thus, Chapter 8 contends that the GSP need only address water quality degradation that is a "direct result of projects or management actions conducted pursuant to GSP implementation:" For the Subbasin, any groundwater quality degradation that leads to an exceedance of MCLs or SMCLs in potable water supply wells or a reduction in crop production in agricultural wells that is a direct result of GSP implementation is unacceptable. Some groundwater quality changes are expected to occur independent of SGMA activities; because these changes are not related to SGMA activities they do not constitute an undesirable result. Therefore, the degradation of groundwater quality undesirable result is: Any exceedances of minimum thresholds during any one year as a direct result of projects or management actions conducted pursuant to GSP implementation is considered as an undesirable result. (Id., underlining added.) This language does not define what constitutes "a "direct result" of GSP implementation or "direct GSA action." Elsewhere, Chapter 8 gives three examples of conditions that may lead to an undesirable result and that the GSA is presumably prepared to address: • Required Changes to Subbasin Pumping. If the location and rates of groundwater pumping change as a result of projects implemented under the GSP, these changes could alter hydraulic gradients and associated flow directions, and cause movement of constituents of concern towards a supply well at concentrations that exceed relevant standards. • Groundwater Recharge. Active recharge of imported water or captured runoff could modify groundwater gradients and move constituents	The water quality SMC primarily focuses on a 'do no harm' approach, whereby groundwater management implemented by SVBGSA will be evaluated for negative impacts to water quality, but no groundwater management implementation will not be evaluated for negative impacts. The phrase 'direct GSA action' has been removed, and replaced with different language after consulting with legal counsel. Existing water quality programs and standards are included in the GSPs to highlight partnership and authority over different groundwater management aspects.

LandWatch Comments	Responses
of concern towards a supply well in concentrations that exceed relevant limits. • Recharge of Poor-Quality Water. Recharging the Subbasin with water that exceeds an MCL, SMCL, or level that reduces crop production could lead to an undesirable result. (Chap. 8, p. 8-57.) Significantly, none of these three conditions that might trigger GSA action include excessive pumping by other parties that may cause water quality degradation; each condition includes only the secondary effects of the GSA's own projects. The GSA's failure to take management action, e.g., its failure to restrict excessive extractions, may also cause water quality degradation. Chapter 8 should be revised to acknowledge that the GSA has both the authority and duty to address groundwater quality degradation caused by excessive pumping. Chapter 8 contends that because other agencies have authority over groundwater quality, the GSA's role is somehow limited: The powers granted to GSAs to effect sustainable groundwater management under SGMA generally revolve around managing the quantity, location, and timing of groundwater pumping. SGMA does not empower GSAs to develop or enforce water quality standards; that authority rests with the SWRCB Division of Drinking Water and Monterey County. Because of the limited purview of GSAs with respect to water quality, and the rightful emphasis on those constituents that may be related to groundwater quantity management activities. Therefore, this GSP is designed to avoid taking any action that may inadvertently move groundwater constituents already in the Subbasin in such a way that the constituents have a significant and unreasonable impact that would not otherwise occur. (Id., pp. 8-59 to 8-60.) The fact that the County and the RWQCB also have authority and responsibility to address water quality degradation demonstrates that the statutory scheme does not rely on the regulatory actions of any single agency. Nothing in SGMA's mandate that the GSP address water quality degradation permits the GSA to consider only the direct effect of GSA projects and only those projects that move pollutants. The GSP	

LandWatch Comments	Responses
must also address the effects of its regulatory omissions, including omissions that move or concentrate existing pollutants by permitting excessive extractions. DWR has made it clear in its imposition of corrective actions on the 180/400-Foot Aquifer Subbasin GSP that "groundwater management and extraction" may result in degraded water quality: RECOMMENDED CORRECTIVE ACTION 5 Coordinate with the appropriate groundwater users, including drinking water, environmental, and irrigation users as identified in the Plan, and water quality regulatory agencies and programs in the Subbasin to understand and develop a process for determining if groundwater management and extraction is resulting in degraded water quality in the Subbasin. Accordingly, the GSP cannot limit its concern to the effects of its own projects without taking responsibility for the effects of unregulated extractions on water quality degradation. For example, if, in the Corral de Tierra Subarea, there is evidence that arsenic concentrations are increased by excessive extractions, then the GSP must manage extractions to avoid undesirable results from increased concentrations. Chapter 8 cannot simply state that "no clear correlation that can be established between groundwater levels and groundwater quality at this time" as if that disposes of the matter. (Chap. 8, p. 8-57.) Indeed, at the July GSA Board meeting, staff acknowledged that lowering groundwater levels could cause water quality degradation, specifically referencing Corral de Tierra. The GSA must investigate, apply the best available science, and manage the resource to prevent undesirable contaminant concentrations caused by excessive extractions.	

Responses to Seaside Watermaster's Comments on the Monterey Subbasin Groundwater Sustainability Plan

Comments Provided on 17 November 2020

Comments from Georgina King of Montgomery & Associates on behalf of the Seaside Watermaster

"I have reviewed and plotted up the water quality data and parts of reports EKI provided. I also looked at MCWRA's recent maps of seawater intrusion (2017). I have pasted some maps and charts into a Word document Essentially, what we see is that:"

Comments	Responses
1. There is Salinas Valley seawater intrusion quite far south and into the Seaside Basin in the 180 ft aquifer equivalent to formations shallower than the Shallow Aquifer (Paso Robles) in the Seaside Basin. But we know this from the induction logs in the northern Sentinel Wells. The data available and included on our map is from Fort Ord monitoring – all of which is very shallow (180-ft aquifer) and not in our Shallow (Paso Robles) aquifer. As reference for depth, the FO-9 shallow aquifer in the Paso Robles is screened from 610-650 ft below ground.	As discussed in the GSP, available data indicates that there is no observed seawater intrusion in the upper portion of the 180-Foot Aquifer. Therefore, MCWRA's maps are only consistent with data collected from the lower 180-Foot Aquifer.
2.The 400 ft aquifer which is equivalent to the Shallow Aquifer (Paso Robles) in the Seaside Basin has a similar southern extent to what we have included in the SIAR mostly because there is no data/wells available to update the extent. There has been considerable inland advancement. <u>There are no 400-foot Fort Ord monitoring wells that have data more recent than 2008. Perhaps we should find out if some of these wells can start being sampled by the GSA in that area? [Underline text are the items that Seaside Watermaster would like the GSP to address.]</u>	There is a large amount of total dissolved solids (TDS) data that was collected from Ford Ord monitoring wells in 2018 that has been used in the seawater intrusion analysis in Chapter 5 (Figure 5-28). As discussed in Chapter 5, there is a high correlation between TDS and chloride results in groundwater in the subbasin, and therefore TDS measurements are a good indicator of seawater intrusion. As discussed in Chapter 7, the area between MCWD-09 and MPMWD#FO-10S remains a data gap. MCWD plan to fill the data gap during GSP implementation by drilling a new well.
<u>3. FO-10 shallow and deep have had almost 15 feet of groundwater level drop over the past 11 years, most of which has been since the start of the drought in 2012. There must be some pumping in this area that is causing this. I do not have the data to help me figure this out. The GSA is going to have to address this.</u>	The decline in groundwater levels in FO-10 is discussed in the GSP. Two possible explanations for the decline are identified in the GSP since there is no identified pumping in this area: (1) these wells are screened within sediments that connect directly to the Deep Aquifers where groundwater levels are declining; or (2) leakage is occurring from the 400-Foot Aquifer into the Deep Aquifers in the vicinity of these wells.
4. To concude, <u>the lack of data available for the 400-ft aquifer (equivalent to Paso Robles aquifer) means we still have a large data gap between the</u>	The GSP identifies this as a data gap and plans to address the data gap by either utilizing an existing well or drilling a new one.

Chapter 5 comments

Comments	Responses
1. There are a huge number of acronyms in this Chapter. Please include near the front of the Chapter a list of acronyms and their meanings.	An abbreviations list is provided in the front of the GSP.
2. I am confused by the many names given to the various aquifers. For example in the Seaside Basin we have 3 aquifers: Aromas Sands, Paso Robles, and Santa Margarita. In the adjacent Monterey Subbasin Marina Management Area there are the upper and lower 180' and 400', the Dunes Sands, and the Deep Aquifers. In the Monterey Subbasin Corral de Tierra Management Area there are the El Toro Principle aquifers. I'm sure many of these are hydrogeologically interconnected and thus, in essence, the same aquifer. Near the front of this Chapter please include a table that gives the corresponding name of the aquifers in each of the Management Areas and the adjacent Seaside Subbasin and the 180/400-foot Subbasin, and a cross-section figure that graphically depicts the aquifers across each of these Management Areas and Subbasins.	Text added under Section 4.2.2.
3. Page 7 - This para includes language indicating that there is a data gap in the southern portion of the Marina-Ord area Dune Sand Aquifer. Language should be added to say that this data gap needs to be filled as part of the GSP.	As discussed in Chapter 4, the SVA pinches out in the southwestern portion of the Marina-Ord Area and therefore the Dune Sand Aquifer is likely hydraulicly connected to the underlying aquifers there. The GSAs' near-term plan to fill-in these data gaps is to install monitoring wells in the 400-Foot and Deep Aquifers in this area, as discussed in Section 7.3.2 and Section 10.2.3.1.
4. Page 8 – This para states that the Dune Sand Aquifer protects the upper 180' aquifer from SWI. Please elaborate on how this protection is provided.	See discussion in Section 5.1.2.1: "Groundwater elevations are near sea level at the coastline and are below sea level further inland. This inland gradient allows high salinity water to flow into the Subbasin (see Section 5.3 Seawater Intrusion). However, inflow from the Dune Sand Aquifer protects the upper 180-Foot Aquifer from seawater intrusion."

Comments	Responses
5. Page 8 – Please explain what is causing the local groundwater depression just north of the boundary between the Seaside Subbasin and the Marina-Ord area. The Watermaster is very concerned that we are starting to see increasing chloride levels in our monitoring well FO-10 which is in that area and also in our monitoring well FO-9 which is inside the Seaside Subbasin not too far south and west of FO-10. For more detail on this please refer to page 33 of the Watermaster's 2020 Seawater Intrusion Analysis Report (SIAR) which is posted at this link: http://www.seasidebasinwatermaster.org/Other/2020%20Seawater%20Intrusion%20Analysis%20Report%20Final%2012-3-20.pdf	The local depression is explained in Section 5.1.3 on page 22, which states: "Two CASGEM wells in the southwestern portion of the Marina-Ord Area, MPWMD#FO-10 and MPWMD#FO-11, show consistent decreasing trends over the past 15-years. Additionally, groundwater elevations in these wells are significantly lower than those to the north near the City of Marina and to the south in the Seaside Subbasin. When water levels in these wells are plotted in conjunction with other 400-Foot Aquifer wells in the Marina Ord Area, they indicate the presence of in a localized depression in the groundwater potentiometric surface of the 400-Foot Aquifer. However, there is no known extraction in the Monterey Subbasin in the vicinity of these wells and groundwater elevations observed in these wells are similar to those measured in the Deep Aquifers. These data suggest that (1) these wells are screened within sediments that connect directly to the Deep Aquifers; or (2) leakage is occurring from the 400-Foot Aquifer into the Deep Aquifers in the vicinity of these wells." MCWD will collect additional data in the vicinity of FO-10 and FO-11 during GSP implementation to future understand the cause of groundwater declines and potential seawater intrusion in this area.
6. Figure 5-3 – The depression referred to on page 8 is clearly shown in this Figure so the response to the comment above about this should also refer to this Figure.	See response above.
7. Figure 5-7 – The groundwater contours for the 400-foot aquifer shown in this Figure extend into the Seaside Subbasin. We do not have a 400-foot aquifer in the Seaside Subbasin. Presumably this is either the Paso Robles or the Santa Margarita aquifer, so the legend of this Figure should make that clarification.	The 400-Foot Aquifer in the Monterey Subbasin is likely connected to the Paso Robles Aquifer in the Seaside Subbasin. Note added to figure for clarification.
8. Figure 5-8 – The groundwater contours for the Deep Aquifers shown in this Figure extend into the Seaside Subbasin. We do not have a Deep Aquifer in the Seaside Subbasin, and the aquifers	The Deep Aquifers in the Monterey Subbasin are likely connected to the Santa Margarita Aquifer in the Seaside Subbasin. Note added to figure for clarification.

Comments	Responses
we do have, with the exception of the Aromas Sands, are all much deeper than the contours that are shown.	
9. Figures 5-9 and 5-10 – There are groundwater level contours in the Laguna Seca Subarea of the Seaside Subbasin that should also be plotted on this Figure, since they correspond to the same aquifers that are part of the El Toro Primary Aquifer. Those contours are contained in the Watermaster's 2017 Seawater Intrusion Analysis Report on pages 54 and 55. For 2017 the link to the SIAR is: http://www.seasidebasinwatermaster.org /Other/2017%20Seawater%20Intrusion%20 Analysis%20Report_Final.pdf	The data and groundwater level contours will be included in future versions of the GSP. Groundwater level data from the Laguna Seca wells are included in the creation of the Corral de Tierra contours. Future maps will extend these contours in this portion of the Corral de Tierra into the Laguna Seca as both an acknowledgement of the hydrogeological connectivity, as well as the importance of collaboration regarding cross-boundary flows..
10. Page 21 – The word "the" is missing in the first sentence of this bulleted para, right before the word "large".	Updated.
11. Page 23 – When the term "El Toro Primary Aquifer System" is first introduced please describe the aquifers that comprise it, and if they are not the Paso Robles and Santa Margarita aquifers, explain how they correspond to those aquifers, which are the ones we monitor in the Laguna Seca Subarea of the Seaside Subbasin.	Addressed in the text. The term El Toro Primary Aquifer System is initially defined in Chapter 4, and includes the Paso Robles Formation, the Santa Margarita Sandstone, and the Aromas Sands (if/where they occur in the Corral de Tierra area). The principal aquifers in the Monterey Subbasin, and neighboring subbasins are derived from the same geologic materials. In the Seaside Subbasin, the principal aquifers are named based on the Paso Robles and Santa Margarita geologic Formations. These two geologic formations are grouped together to form the El Toro Primary Aquifer System in the Corral de Tierra area as many wells are screened across both formations. The hydraulic connection between the Corral de Tierra area and the Laguna Seca area is relatively well established with production wells screened in the Paso Robles and Santa Margarita Formations with "shallow" designations generally correlating to wells completed in the Paso Robles formation and "deep" designations generally correlating to wells completed in the Santa Margarita formation.
12. Figure 5-13 – The plots in this Figure of MPWMD#FO-10 and MPWMD#FO-11S show	See response to Comment 5.

Comments	Responses
falling groundwater levels, whereas the other plots in this Figure should stable levels. The reason for the falling levels in these wells, which are in the southwestern portion of the Marina-Ord area, should be explained in the text.	
13. Figure 5-14 – This Figure shows groundwater levels in the Deep Aquifers. The plot for MPWMD#FO-10D shows groundwater levels in the Santa Margarita aquifer, not the Deep Aquifer. I am not sure, but the same may be true of MPWMD#FO-11D.	As discussed in Section 4.2.2.1.7 Deep Aquifers (page 35 of Chapter 4): "Within the Monterey Subbasin, the Deep Aquifers comprise the middle and lower portions of the Paso Robles Formation, the Purisima Formation and the Santa Margarita Sandstone (Hanson et al., 2002; Yates, 2005). The Deep Aquifers are also likely connected to the deep Santa Margarita aquifer in Seaside Subbasin (Yates, 2005)." Therefore, groundwater levels in MPWMD#FO-10D and MPWMD#FO-11D are plotted with other Deep Aquifers within the Monterey Subbasin.
14. Figure 5-18 – The text should discuss the dramatic decline in groundwater elevations occurring since 1998, and a trend line for that portion of the data would be helpful to highlight the rate of decline.	The average rate of decline in groundwater levels in these wells will be added to figure.
15. Figure 5-20 – There is considerably more groundwater level measurement data in the Seaside Subbasin than is depicted in this Figure. That data is available in the Watermaster's annual SIARs and should be added to this Figure, just as the data in the 180/400-foot Aquifer Subbasin is shown.	Noted. The GSP focuses on creating contours for the Monterey Subbasin, and therefore this map only includes wells located in the portion of the Seaside Subbasin that is adjacent to the Monterey Subbasin.
16. Page 37 – A paragraph should be added within the discussion of the AEM data describing the comments and concerns about the reliability of the AEM data which were raised by the Blue Ribbon Panel that reviewed the Cal Am Slant Well reports.	The 2017 AEM Study[1] and 2019 AEM Study[2] for the Monterey Subbasin and surrounding area were performed by highly regarded professors of Geophysics and California Licensed Geophysicists including: • Dr. Rosemary Knight, Ph. D.: Professor of Geophysics at Stanford University,

[1] Stanford/Aqua Geo Frameworks, 2018. *Interpretation of Hydrostratigraphy and Water Quality from AEM Data Collected in the Northern Salinas Valley, CA*, Ian Gottschalk, Rosemary Knight, Stanford University, Stanford, CA; Ted Asch, Jared Abraham, Jim Cannia, Aqua Geo Frameworks, Mitchell, NE, dated 15 March 2018.

Comments	Responses
	• Theodore H. Asch, CA GP#1038; California Licensed Professional Geophysicist with Aqua Geo Frameworks, LLC. • Jared D. Abraham CA GP#1089: a California Licensed Professional Geophysicist with Aqua Geo Frameworks, LLC. The 2017 AEM study has been peer reviewed and has been validated against lithologic and water quality data within the Monterey Subbasin[3]. Both studies have also been provided to California Department of Water Resources (DWR) for review as part of a large new AEM Study that is being conducted by DWR across California. One of the primary authors of the 2017 AEM study, Dr. Ian Gottschalk, Ph. D., is one of the geophysicist working on DWR's study.
17. Page 41 (Next to last para) – A sentence should be added at the end of this para stating that there is also a data gap in the southwestern portion of the Marina-Ord area, which prevents knowing the location of the SWI front in that area as well.	Two Fort Ord monitoring wells that screen the 400-Foot Aquifer near the seawater intrusion front in Figure 5-28 were sampled for total dissolved solids and chloride in 2018, which indicates no sign of seawater intrusion. Thus, data gap in the southwestern portion of the Marina-Ord area was not discussed here. However, Chapter 7 identifies this area as data gap to monitor future seawater intrusion, and this data gap will be filled during GSP implementation by either identifying an existing well in each area that meets the criteria for a valid monitoring well, or drilling a new well in each area, as further described in Chapter 10.
18. Figure 5-24 – In the legend the "Note" pertaining to the Groundwater with TDS <1,000 mg/L is missing.	Note 2 is updated in the latest figure.
19. Figure 5-28 – The text where it discusses this Figure should note that the Watermaster's Sentinel Well SBWM-1, which is located next to the coast just north of the Seaside-Marina-Ord boundary has not shown any indication of SWI in any of the aquifers that it penetrates, which include the Paso Robles and Santa Margarita	Although water quality results from SBWM-1 did not indicate seawater intrusion, its well screens are located greater than 1,000 ft bgs. Induction logs from SBWM-1 showed low resistivity and possible seawater intrusion around 400-700 ft bgs which corresponds to the approximately depth of the 400-foot aquifer and the depths of

[3] Gottschalk, I., Knight, R., Asch, T., Abraham, J. and Cannia, J., 2020. Using an airborne electromagnetic method to map saltwater intrusion in the northern Salinas Valley, California. Geophysics, 85(4), pp.B119-B131. https://library.seg.org/doi/full/10.1190/geo2019-0272.1

Comments	Responses
aquifers. Therefore, it is not clear why the extent of the "Area of Known Seawater Intrusion" is shown going into that area. Due to the lack of monitoring well data in that area (as mentioned in some of the comments above) it is not clear how the extent of the SWI front can be accurately depicted in that part of the Marina-Ord area. This is supported by the MCWRA SWI mapping in Appendix 5B which has "???" shown in that area due to lack of data. This comment also applies to Figure 5-29 which also shows the "Area of Known Seawater Intrusion".	the inland MPMWD#FO-10S well screen (650 ft bgs). These data indicate that seawater intrusion potentially exists in the 400-Foot Aquifer (or shallow Paso Robles Aquifer) at this location. The seawater intrusion extent for the remainder of the Subbasin is drawn based on data shown on this figure, including a 2018 sampling event conducted by MCWD from FO monitoring wells to fill data gaps, in addition to wells that are regularly monitored by MCWD and MCWRA.
20. Page 48 – Next to last para - A sentence should be added at the end of this para stating that Wells MPWMD#FO-9 and FO-10 have also been showing increasing TDS levels in recent years.	The following text has been added: "One CASGEM well in the southwestern portion of the Marina-Ord Area, MPWMD#FO-10, showed a recent increase in TDS concentration in 2020. Induction logging at this well suggested that the increase in TDS concentration was no due to casing leakage. However, the exact cause of the elevated TDS/chloride concentration is unknown. The GSAs will collect additional data in the vicinity of this well during GSP implementation in collaboration with the Seaside Basin Watermaster. "
21. Page 48 – Last Para - Provide a para here that discusses the apparent migration of SWI from the Marina-Ord area, south toward the Seaside Subbasin, as discussed in the Watermaster's 2020 SIAR.	See response above. The GSA is making a priority to conduct future investigation of the seawater intrusion extent in the southern portion of the Marina-Ord Area, west of FO-10S.
22. Figure 5-29 – Add an inset plot of TDS levels from well MPWMD#FO-9 to this Figure	Per the Geophysical Investigation Fort Ord Monitoring Wells FO-9 and FO-10 – Preliminary Findings Memo provided by the Seaside Basin Watermaster on April 22, 2021, recent water quality results from MPWMD#FO-09 were impacted by a structural flaw in the casing, which suggests that the samples taken in recent years are not representative of the in-situ aquifer water from the screened interval at this well.
23. Page 50 – Add MPWMD and the Watermaster as entities from which data was collected.	Added.

Comments Provided on 22 April 2021

Monitoring Well FO-10 Induction Logging Results and Request

Comments	Responses
1. Attached is the Tech Memo prepared by Martin Feeney after the recent completion of induction logging of monitoring wells FO-9 and FO-10. As his Memo reports, he does not have an explanation for the findings in FO-10 in which the logging showed high conductivity over nearly the entire depth of the well, whereas the E-log from the original construction of this well did not show this. One theory, that there is leakage in this casing just as is believe to be the case in the casing of FO-9, does not bear out, since there are clearly different water level readings in the different depth wells at FO-10. That indicates that these wells are not cross-connected through casing leakage. Our TAC asked that you please include investigating the cause of these findings in the GSP for this portion of the Monterey Subbasin, and developing any response action that the investigation finds should be taken.	Additional language has been added to the latest draft, under Section 5.3.4 Historical Progression of Seawater Intrusion.
2. With regard to FO-9 Shallow, MPWMD plans to video inspect this well to confirm the suspected casing leakage in FO-9 Shallow and to determine the structural integrity of FO-10 Shallow. They plan to do that work in the next couple of weeks and I will share with you the results of that inspection. If it is found that the casing in FO-9 Shallow is leaking, and that it is not feasible to repair it, MPWMD said that as the owner of the well they plan to destroy it to avoid having it be a cross-aquifer contamination source. Since water level and water quality data from that part of the Seaside Basin is important not only to the Watermaster and MPWMD, but also to MCWD to provide information for your development of the Monterey Subbasin GSP, if the well needs to be destroyed we would like to discuss with you a cost-sharing arrangement to have a replacement monitoring well installed near that location. "One correction. The District is planning to video FO-09 shallow and deep and not FO-10."	Noted.

Comments Provided on 10 May 2021

Comments on Chapter 7

Comments	Responses
1. Section 7.3 – This section states in part "The sustainability indicator for chronic lowering of groundwater levels is evaluated by monitoring groundwater elevations in designated monitoring wells." The list of entities that monitor the 39 wells mentioned here does not include the Watermaster. The Watermaster has numerous wells that are adjacent to the Corral de Tierra subarea, and some that are adjacent to the Marina- Ord subarea. Those should be included in order for the GSP to be able to see how its management actions are affecting the adjacent subbasin.	The 39 wells identified in Chapter 7 are Representative Monitoring Site (RMS) wells. As described in Section 7.1.2, RMSs are a subset of the monitoring network and are focused on monitoring groundwater condition relative to SGMA compliance. The GSAs are required to limit RMS to wells located within the Monterey Subbasin. However, groundwater level data from the wells outside the Monterey Subbasin are included in the creation of the GSP's analysis, e.g. groundwater elevation contours, and development of the basin numerical model. MCWD GSA and SVBGSA will continue coordinating with the Seaside Basin Watermaster to monitor groundwater elevations and water quality in the Seaside Subbasin. These data will be included in future version of the GSP and in annual reporting. Chapter 7 focuses on discussing monitoring network within the Monterey Subbasin. Clarifying language has been added to Section 7.1.
2. Section 7.3 – The 3rd bullet on this page states "RMS wells should facilitate monitoring along the existing seawater intrusion front to verify that water levels in these areas are not declining and increasing the risk of seawater intrusion." Monitoring Well FO-9 is within the Seaside subbasin, just south of the boundary with the Monterey subbasin, and is near the known seawater intrusion front. Therefore, it should be included as an RMS well.	See response to Comment 1.
3. Figure 7-12 and Figure 7-13 – Figures 7-4 and 7-5 should include Monitoring Well FO-9 Shallow and/or FO-9 Deep for the reasons stated above.	See response to Comment 1.
4. Figure 7-6 – Figure 7-6 should include adjacent monitoring wells in the eastern portion of the Laguna Seca subarea of the Seaside subbasin to see how Corral de Tierra management actions are affecting the adjacent subbasin. Montgomery &	The data and groundwater level contours will be included in future versions of the GSP. The groundwater level data from the Laguna Seca wells are included in the creation of the Corral de Tierra contours. Future maps will extend these

Comments	Responses
Associates has maps showing the names and locations of those wells.	contours in this portion of the Corral de Tierra into the Laguna Seca as both an acknowledgement of the hydrogeological connectivity, as well as the importance of cross-boundary collaboration.
5. Section 7.3.2 – The statement from one of the reports cited in this section that 0.2 to 10 wells per 100 square miles is the recommended monitoring well density is ridiculous for purposes of performing any type of reliable groundwater modeling. Far greater well density is necessary for that purpose.	The current monitoring network include 35 wells in the Marina-Ord Area and 13 wells in the Corral de Tierra Area, which is at far greater density than what the reports suggested.
6. Section 7.3.2 – On this page there is the statement "…additional wells are necessary to provide additional groundwater elevation data near the ocean in areas subject to sea water intrusion." It also states that the generalized locations for monitoring wells was based on "Demonstrating conditions at Subbasin boundaries." For the reasons stated above Monitoring Well FO-9 should be included.	See response to Comment 1.
7. Section 7.3.2 – On this page it states "A higher density of monitoring wells is recommended near residential areas or other locations where groundwater withdrawal is significant" and that this is the case in the Corral de Tierra subarea. Per the comment above on page 7-14 the adjacent monitoring wells in the Laguna Seca subarea should be included.	The data and groundwater level contours will be included in future versions of the GSP. The groundwater level data from the Laguna Seca wells are included in the creation of the Corral de Tierra contours. Future maps will extend these contours in this portion of the Corral de Tierra into the Laguna Seca as both an acknowledgement of the hydrogeological connectivity, as well as the importance of cross-boundary collaboration. The Laguna Seca Monitoring wells will be included in the monitoring network, but will not be included in the RMS network, which must use wells within the subbasin boundaries.
8. Figure 7-7 – Although not within the area identified on Figure 7-7 as a "data gap" area, Monitoring Well FO-9 Shallow should be included to help fill that gap.	See response to Comment 1.
9. Figure 7-8 – Although not within the area identified on Figure 7-8 as a "data gap" area, Monitoring Well FO-9 Deep should be included to help fill that gap.	See response to Comment 1.
10. Figure 7-9 – Per the comment above on page 7-14, the adjacent monitoring wells in the Laguna Seca subarea should be included in Figure 7-9.	See response to Comments 4 and 7.

Comments	Responses
11. Section 7.3.3 – In the top para on this page it appears that the word “parallel” should be “perpendicular.” In the 2nd para after the words “…Monterey Subbasin…” the words “…or into any adjacent subbasins…” should be inserted. In that same para the word “southeastern” should be replaced with the word “southern.” In the last para on this page, after the words “Monterey Subbasin” the words “…and in the adjacent Seaside Subbasin…” should be inserted.	Latest draft has been updated per this comment except replacing the word “parallel” with “perpendicular”. As shown on Figure 5-28 in Chapter 5, the current hydraulic gradient and groundwater flow direction is parallel to the seawater intrusion front. Therefore, only minimal migration of seawater intrusion within the Monterey Subbasin was observed during the past two decades.
12. Figure 7-10 – In Figure 7-10 in the Legend this is a symbol for “Area of Potential Seawater Intrusion.” It would be helpful to discuss in the text how that area was determined.	Figure 7-10 shows the same extent as Figure 5-28, please see Chapter 5 for details. A note was added to Figure 7-10 for clarification.
13. Section 7.5 – In the top para the words “…and the Seaside Groundwater Basin Watermaster…” should be added after the word “MPWMD.” In that same para it states “Additional sites are added to the RMS network to facilitate monitoring of significant and unreasonable groundwater conditions…” This supports the need to add monitoring wells in the adjacent Seaside subbasin.	Language added, and see response to Comment 1.
14. Section 7.5 – The Seaside Groundwater Basin Watermaster should be added to the list of monitoring agencies on this page. Per comments above Monitoring Well FO-9 Shallow should be added to Figure 7-15. Per comments above Monitoring Well FO-9 Deep should be added to Figure 7-16. Per comments above Monitoring Wells FO-9 Shallow and Deep should be added to Table 7-4.	See response to Comment 1.
15. Section 7.5 (Page 7-37) – Sentinel MW#1 is also monitored by the Seaside Groundwater Basin Watermaster via induction logging and datalogger groundwater elevation monitoring.	Noted and added to the latest draft.
16. Section 7.5.1 – In the 2nd bullet in this section correct the wording to read “The Seaside Basin Watermaster Monitoring and Management Program…”	Updated.
17. Section 7.5.2 – In the 1st and 2nd bullets in this section add that Monitoring Well FO-9 should be included.	See response to Comment 1.
18. Section 7.6 (Figure 7-17) – In Figure 7-17 monitoring wells in the eastern portion of the	See response to Comments 4 and 7.

Comments	Responses
Laguna Seca subarea should be added to the wells in the groundwater quality monitoring network.	
19. Section 7.6.2 – The statement that the network cannot be expanded by drilling new wells (i.e. monitoring wells) does not make sense.	This sentence was rephrased.

Comments Provided on 13 July 2021

Comments on Chapter 8

Comments	Responses
1. Section 8.4 – The 3rd para on this page talks about SMCs in this subarea and their potential to impact SMCs in adjacent subbasins (in this case the Seaside subbasin). It goes on the say that SMCs for the Monterey subbasin will be set so as to be consistent with SMCs in those adjacent subbasins, so that adjacent subbasins will be able to be sustainable. For this reason it would be appropriate (as mentioned in other comments below) for the monitoring network of the Monterey subbasin to include some monitoring and/or production wells in the Seaside subbasin that are near the border between the two subbasins. Data from those wells can be provided to the SVBGSA at no cost, so the SVBGSA can determine what impact the Monterey subbasin's SMCs are having on the Laguna Seca subarea of the Seaside subbasin, which is the portion of the Seaside subbasin that abuts the Corral de Tierra subarea. This para also mentions that modeling will be one of the means of determining the impacts of the Corral de Tierra SMCs on the adjacent subbasin. The Monterey subbasin model being developed for the MCWDGSA by its consultant EKI should incorporate modeling information from the Seaside Watermaster's Seaside Basin Model (prepared by HydroMetrics) to ensure that the two models are consistent at the boundary between the subbasins.	The data and groundwater level contours are included in the Monterey Subbasin Model, and future data from the Laguna Seca area will continue to refine the model during implementation, as well as for monitoring over the GSP planning period. The GSP has been developed in coordination with vested stakeholders, including those in neighboring basins. Projects have been developed, and will be included in future modeling scenarios and as implementation data are collected. Modelers are continuing to collaborate to improve the understanding of the relationship between Laguna Seca and the Corral de Tierra. As described in detail in Appendix 6B, there are notable differences in hydrogeologic conceptualization and geometry between the MBGWFM and the Seaside Model. a few simplifying assumptions had to be made to effectively link head outputs from the Seaside Model to general head boundary cells along the Seaside boundary within the MBGWFM. The basin GSAs will continue to collaborate with the Seaside Subbasin to further rectify the discrepancies between the two models in a future update to the MBGWFM, and/or to integrate both models into a regional model that covers both subbasins.
2. Table 8-1 – The Corral de Tierra area MT and MO groundwater elevations (2015 and 2008) are believed, based on modeling performed for the Watermaster by HydroMetrics, to be so low that they are causing water to (1) be drained out of	The current model shows approximately 400 AF/yr. flowing from the Corral de Tierra area into the Laguna Seca area.

Comments	Responses
the Seaside subbasin's Laguna Seca Subarea by creating an eastward sloping hydraulic gradient and/or (2) preventing the natural westward flow of groundwater from replenishing the Laguna Seca Subarea, resulting in falling groundwater levels in that subarea. The GSP should mention this and ensure that its SMCs prevent this adverse condition from continuing.	It is important to note that multiple projects need to be implemented in the Corral de Tierra area in order to meet the sustainability goals. Declining water levels have been observed in this area since the early 1990's. The effort to raise groundwater levels in the Corral de Tierra area and neighboring Laguna Seca area will be a sustained and coordinated effort among managers and stakeholders. Additionally, modelers are continuing to collaborate to improve the understanding of the relationship between Laguna Seca and the Corral de Tierra areas. The modeling performed by HydroMetrics in 2016 has a different set of assumptions and boundary conditions than the modeling performed by EKI. These models will be revised through a series of meetings with the modelers to better align assumptions, boundary conditions, and predictions over time.
3. Section 8.7.1 – Reword the first bullet on this page to read "Groundwater elevations at or below those observed in 2015. Lower groundwater elevations could lead to inadequate water production in a significant number of domestic and small water system wells, <u>not only in the Corral de Tierra subarea but also in the Laguna Seca subarea of the adjacent Seaside subbasin.</u>	Updated.
4. Section 8.7.1 – This Section discusses a minimum threshold of 20% exceedances of groundwater levels. As mentioned in the comment above on page 8-8, some monitoring wells in the Laguna Seca subarea, which is directly impacted by groundwater levels in the Corral de Tierra subarea, should be included in Representative Monitoring Sites for the Corral de Tierra subarea when making the 20% calculation.	The Seaside data and groundwater level contours will be included in future versions of the GSP. The groundwater level data from the Laguna Seca wells are included in the development of the Corral de Tierra contours. Future maps will extend these contours in this portion of the Corral de Tierra into the Laguna Seca as both an acknowledgement of the hydrogeological connectivity, as well as the importance of cross-boundary collaboration. The Laguna Seca Monitoring wells will be included in the monitoring network, but will not be included in the RMS network, which must use wells within the subbasin boundaries. The effort to monitor groundwater levels in the Corral de Tierra area and neighboring Laguna

Comments	Responses
	Seca area will be a sustained and coordinated effort among managers and stakeholders.
5. Section 8.7.2.3 – The bottom para on this page mentions undesirable results caused by chronic lowering of groundwater levels within the Corral de Tierra subarea. The following language should be inserted at the appropriate place in this para "These same undesirable effects will occur in the adjacent Laguna Seca subarea from chronic lowering of groundwater levels in the Corral de Tierra subarea."	Language added with modifications.
6. Section 8.7.2.3 – The top para on this page mentions the term "clustering". A better explanation of what would constitute "clustering" should be added to this para, since this is apparently going to be one of the criteria to determine if a significant and unreasonable effect is occurring.	Comment noted.
7. Table 8-2 – Many of the wells in this table also have common names which appear on maps in various reports that have been prepared for the Corral de Tierra and Laguna Seca subareas. A column should be added to this Table titled "Well Common Name" to include that information for the reader's ease of knowing which well in located at the Monitoring Site. Also, as mentioned in the comment above on page 8-8, some monitoring wells in the Seaside subbasin should be included in this Table. Suggested wells for inclusion are: MPWMD#FO-5S, MPWMD#FO-5D, MPWMD#FO-6S, MPWMD#FO-6D, Seca Place, MPWMD#FO-9S, MPWMD #FO-9D,	Table 7-1 in Chapter 7 contains the common name of the RMS wells. This table lists SMCs established in RMS wells pursuant to SGMA. The Seaside monitoring wells will be included in the monitoring network, but not be included in the RMS network, which must use wells within the subbasin boundaries. MCWD GSA and SVBGSA will continue coordinating with Seaside Basin Watermaster to monitor groundwater elevations and water quality in the Seaside Subbasin and will include data from Seaside monitoring wells in annual reporting. The long-term sustainability goal strives to raise water levels and not adversely impact the Seaside Subbasin.
8. Figures 8-4 and 8-5 – The wells suggested for inclusion in the comment on page 8-21 (MPWMD#FO-9S and MPWMD #FO-9D) should be added to these figures to monitor the effectiveness of the SMCs in the Marina-Ord subarea on preventing seawater intrusion from flowing into the Seaside Subbasin.	See response to Comment 7.
9. Figure 8-6 – The wells suggested for inclusion in the comment on page 8-21 (MPWMD#FO-5S, MPWMD#FO-5D, MPWMD#FO-6S, MPWMD#FO-	See response to Comment 7.

Comments	Responses
6D, and Seca Place) should be added to these figures to monitor the effectiveness of the SMCs in the Corral de Tierra subarea on preventing chronic lowering of groundwater levels in the Seaside Subbasin.	
10. Section 8.7.3.1 – The next to the last para on this page states "The declining groundwater elevations in the Deep Aquifer may be causing groundwater elevations to fall within the 400-Foot Aquifer in the southwestern portion of the Marina-Ord Area (i.e., near wells MPWMD#FO-10S and MPWMD#FO-11S)." An explanation to support this hypothesis should be included as this is not intuitively apparent.	This is discussed under Section 5.3.1 (see response to Comment 5 for Chapter 5, provided on January 8, 2021). Additional languages were included in the GSP to provide clarification.
11. Section 8.7.3.1 – In the top two paras there are two small typos to correct: (1) in the first para the word "elevations" should be singular; (2) in the second para the last sentence should be reworded in part to read "…Deep Aquifer's wells as well as…"	Updated.
12. Section 8.7.3.1 – The second bullet on this page mentions historical groundwater elevation data from wells monitored by MCWRA. This language should be expanded to include historical groundwater elevation data from wells monitored by the Seaside Basin Watermaster.	Updated.
13. Section 8.7.3.5 – Add at the end of the first sentence at the top of this page the following wording "…including the occurrence of "Material Injury" (as defined in the Seaside Basin adjudication decision) in the Laguna Seca subarea due to lowered groundwater levels."	Updated.
14. Section 8.7.4.1 – Correct "MPWMD" to read "MPWMD" for the wells mentioned in this Section and the footnote at the bottom of this page. Also, update the language in the footnote to read as follows: "Chloride concentration measured from MPWMD#FO-10S and MPWMD#FO-09S in September 2020 were 89.9 mg/L and 90.4 mg/L, respectively. <u>An investigation performed by MPWMD into the cause of this in mid-2021 concluded that there was leakage in the upper portion of the casing that was allowing salty shallow dune sand water to flow downward in this well, thus causing these increases in chloride readings.</u> As part of	"MPWMD" has been corrected. It is our understanding that the leakage in the casing was only confirm in MPWMD#FO-09, and the cause for elevated chloride in MPWMD#FO-10 was still unknown.

Comments	Responses
GSP implementation, the Subbasin GSAs intend to investigate possible seawater intrusion near the southwestern portion of the Marina-Ord Area in collaboration of the Seaside Watermaster.”	
15. Section 8.7.4.2 – In the 2nd para on this page there is discussion about groundwater elevation trends continuing to fall in the early part of the implementation period and then recovering in the latter part of that period. It would helpful to the reader to have an explanation included as to how the rate of recovery of the fallen groundwater levels was determined, and what the level of confidence is in these projections. In other words, is it certain that the projects that will be included in Chapter 9 of the GSP will be able to bring groundwater levels up as shown in the figures in Appendix 8B?	The interim milestones for wells with declining groundwater elevations are determined based on the anticipation that time will be required to implement these projects and management actions. The GSA plans implement projects and management actions, including those listed in Chapters 9 and 10, to achieve these goals. As shown by the water budget and projected groundwater elevation change results in Sections 6.5 and 9.6. As such, a coordinated and sustained approach to sustainable groundwater management will be required between subbasins within the Salinas Valley Basin.
16. Section 8.8.3.1 – There is a table showing estimated groundwater storage in the Marina-Ord area, but I did not see a similar table for the El Toro area.	SVBGSA has chosen to leave this out and focus instead on working towards/attaining the SMC in the GSP. An estimation of groundwater storage may distract from the work on sustainability, and does not include the nuance of accessible groundwater storage.
17. Section 8.8.3.4 – This para discusses the setting of minimum thresholds to avoid dropping below recent levels of storage. The existing groundwater levels in the Corral de Tierra subarea are already causing a loss of groundwater in the Laguna Seca subarea of the Seaside subbasin. Therefore, the Corral de Tierra groundwater levels need to be raised, not just kept from falling further.	The long-term sustainability goal strives to raise water levels and not adversely impact the Seaside Subbasin. The minimum thresholds were set by the Subbasin Committee. The effort to raise groundwater levels in the Corral de Tierra area and neighboring Laguna Seca area will be a sustained and coordinated effort among managers and stakeholders. The long-term sustainability goal will strive to raise water levels and not adversely impact the Seaside Subbasin.
18. Sections 8.10.1 and 8.10.2 – Question: If a water quality problem already exists and therefore the affected part of the subbasin is not sustainable as a potable water supply due to that problem (example of arsenic) doesn’t SGMA require GSPs to include projects and management actions to remedy the problem in order to achieve sustainability?	Based on inputs collected from stakeholders including those from the Corral de Tierra committee, current water quality conditions in the Subbasin have not be determined as significant and unreasonable. In addition, SGMA does not require addressing water quality impacts that existed prior to the establishment of SGMA, such as the arsenic issues mentioned here.

Comments	Responses
19. Section 8.10.3.1 – Small typo to correct in the first para of this Section: put a comma rather than a period after "Monterey County" and make the word "because" not be capitalized.	Updated.
20. Section 8.10.3.1 – Under the "Public water system supply wells regulated by the SWRCB DDW" shouldn't the smaller private systems that are not regulated by DDW, of which there are many in the Corral de Tierra subarea, also be included in the development of the SMCs because of their cumulative impact on the subbasin?	The pumping for *de minimis* and small system wells was approximated based on number of households using land use type, acreage, and parcels.
21. Figure 8A-9 and 8A-10 in Appendix A – The wells suggested for inclusion in the comment on page 8-21 (MPWMD#FO-9S and MPWMD #FO-9D) should be added to these figures to monitor the effectiveness of the SMCs in the Marina-Ord subarea on preventing seawater intrusion from flowing into the Seaside Subbasin.	See response to Comment 1.
21. Figure 8A-11 and 8A-12 in Appendix A – The wells suggested for inclusion in the comment on page 8-21 (MPWMD#FO-5S, MPWMD#FO-5D, MPWMD#FO-6S, MPWMD#FO-6D, and Seca Place) should be added to this figure to monitor the effectiveness of the SMCs in the Corral de Tierra subarea on preventing chronic lowering of groundwater levels in the Seaside Subbasin.	See response to Comment 7.

Draft Chapter 8 – Supplemental Comments from Seaside Basin Watermaster 7-30-21

These are comments provided by the Watermaster's hydrogeologic consultant, Montgomery & Associates. They supplement the Watermaster's comments dated 7-13-21.

Comments	Responses
1. Figure 8-6 – The Robley wells are the ones to focus on to understand what would happen in the Seaside Basin than the wells on Figure 8-6 that are much farther away from the Seaside Basin. The minimum threshold for the Robley wells are just above record lows in 2020 on the hydrographs (levels this year are undoubtedly going to be even lower!). The GSA has 20 years to get levels at or above the minimum threshold, so levels can still fall lower than they are now between now and 2042.	Comment noted.
2. Figures 8-9 and 8-10 – We don't find the contours on Figures 8-10 and 8-11 very useful because we don't have contours generated the same way for the Seaside Basin (i.e., based on an assumed future condition). The flow direction from the contours is similar to current conditions (see Chapter 5, Figures 5-9 and 5-10) so there is no expected change in flow directions to what has happened in the past. What I found more informative was Figure 8-6 which shows historical hydrographs for the Robley wells together with minimum threshold (elevation that they should not really be going below) and the measurable objective (elevation where they would like to be). Note that the measurable objective is not enforceable but the minimum threshold is.	Comment noted.
3. Figure 8-12 – The example well in Figure 8-12 shows a continuing drop in groundwater levels, with levels only increasing to measurable objectives after 2030 when project benefits are projected to kick in.	The interim milestones included in the Monterey GSP reflect the reality that it will take time to implement projects and management actions to stop groundwater levels from falling and increase levels. As discussed in the GSP, rates of groundwater extraction within the Monterey Subbasin are significantly lower than total recharge, and large volumes of groundwater are flowing into the 180/400-Foot Aquifer Subbasin. As such, sustainability with the Monterey Subbasin will require the implementation of both local and regional projects and management actions to reach sustainability. Such regional solutions will inevitably take time to implement.

Comments	Responses
	The Monterey GSP is consistent with SGMA, which acknowledges this reality and allows 20 years to reach sustainability.
4. Table 8-3 – Table 8-3 provides interim milestone every five years to show how they project levels will eventually meet measurable objectives. This all indicates that groundwater levels in the Laguna Seca subarea will continue to fall for at least the next 10 years.	See response to Comment 3. The long-term sustainability goal will strive to raise water levels and not adversely impact the Seaside Subbasin.
5. Section 8.7.3.5 – Effect of Minimum Thresholds on Neighboring Basins and Subbasins is an important section to look at – I do not feel they have adequately addressed effects on the Seaside Basin from the minimum thresholds. They do not mention the ongoing declines in the Laguna Seca subarea and what the minimum thresholds will do for that nor the impacts that will occur when levels are allowed to fall lower than the minimum threshold over the next 10 years. There is only one sentence addressing Seaside Basin and it reads "The Seaside Subbasin is an adjudicated basin and not subject to SGMA. The subbasin GSAs have and will continue to coordinate closely with the Seaside Watermaster to ensure that the Monterey Subbasin minimum thresholds do not prevent the Seaside basin from meeting its adjudication requirements."	See response to Comments 3 and 4.
6. There is still the ongoing issue in the Coral de Tierra subarea of poor pumping records. This means they still don't understand exactly what is causing the ongoing declines. Derrik mentioned that they are talking about expanding the County groundwater extraction monitoring (GEMS) into the Corral de Tierra subarea, but that section of the GSP has not been posted yet (probably Chapter 10).	Corral de Tierra groundwater pumping demands were estimated for small water systems and domestic wells by SVBGSA using extraction reported to MCWRA and SWRCB where available, and approximated based on number of households to account for small water systems connections and *de minimis* pumpers using land use type, acreage, and parcels. During Implementation, the GEMS program will be expanded and enhanced to collect more data. This data will continually be refined over the implementation period.

Draft Chapter 9 – Comments from Seaside Basin Watermaster 8-23-21

Comments	Responses
1. Section 9.1 – In the next to last sentence in the first para of this Section please insert after the words “Corral de Tierra Management Areas” the words “and the adjacent Seaside Subbasin”.	“Chronic lowering of groundwater levels sustainability indicator” is a term for the SGMA Act, and since MCWD SGA and SVBGSA do not have the authority to monitor wells located in the Seaside Subbasin, the proposed language will not be added to this paragraph. However, MCWD GSA and SVBGSA will continue coordinating with Seaside Basin Watermaster to monitor groundwater elevations and water quality in the Seaside Subbasin and will include data from MPWMD#FO-9 in the annual reporting.
2. Table 9-1 – Multi-basin project R3 states that multi-basin benefits have not been quantified. Without some indication of the level of benefit a Project may be able to provide, decision-makers will not know which ones are the most desirable projects to pursue.	Though the multi-basin benefits have not been quantified in Table 9-1, Section 9.4.3.2 quantifies benefits including evapotranspiration reduction and additional recharge from four recharge basin. Additional benefits would be quantified through further investigation.

3. Table 9-1 – General comment and recommendation: Many of the Projects and Management Actions do not have estimated Costs or estimated Unit Costs provided for them. Recognizing that some projects are essentially only conceptual at this point, nevertheless, an effort should be made, even if it is as simple as "rule of thumb," to estimate what the range of unit costs might be for each project. Without estimated costs it will be impossible for an operating budget for the GSP to be developed, or for fees or water-use related charges to be developed. As was commented on, and I believe correctly so, by some in the SWIG when Derrik presented a summary of the comments received from the TAC for the SWIG when they discussed various projects that would help mitigate seawater intrusion, it is appropriate to do a "reality check" on projects in terms of getting a sense of how financially feasible they may be. Something like a cost-benefit ratio for example. Without sufficient estimated costs and benefits for each project, time and effort will be wasted evaluating projects that have such high cost-to-benefit ratios that they should be dropped out of the Project list early-on. As a corollary, years ago when projects that could help to solve the water-shortage problem of the Monterey Peninsula were being discussed, and no project was supposed to be rejected out-of-hand even if it seemed extremely unlikely, a project to tow icebergs from the Arctic to Monterey Bay so the water could be melted and used as a water supply for the Peninsula was proposed. Time and effort was spent coming to the conclusion that it was simply economically and/or logistically infeasible. The same can be said about a number of the proposed projects which have very high implementation costs and very little water-savings benefit, resulting in very high unit costs. I recommend that a separate table showing just: • P/MA # • Project Name • Quantity of water that will be saved from being pumped • Implementation and O&M costs • Unit Cost	Comment noted. Cost for all projects and management actions are estimated under each of the project descriptions and summarized in Table 9-1 under the "cost" column, including capital costs, O&M costs, and unit costs if applicable. Project benefit and capacity are summarized under the "Project Benefits / Quantification of Benefits" column. As further discussed in Section 10.5, the basin GSAs will further assess project benefit and feasibility during the first two years of GSP implementation. The GSAs will continue to collaborate with the Seaside Watermaster and key agencies during that process.

• A priority ranking column (which would be filled in by the GSP Committee based on the data in the other columns of this table)	
4. Table 9-1 – The Pumping Allocation and Control Management Action will almost certainly be an action/project that will have to be implemented to achieve Corral de Tierra subbasin sustainability. This Management Action will have to achieve the greatest amount of pumping reduction, since all of the other Projects and Management Actions combined, especially after those that are financially infeasible are eliminated, will fall far short of achieving the necessary pumping reduction. Therefore, instead of saying "Decreased extraction; range of potential benefits" in the "Project Benefits/ Quantification of Benefits" column, an amount of pumping reduction should be shown for this Management Action, so the reader can see clearly the magnitude of pumping allocation and control that will be needed.	A "No Pumping" Project scenario was run with the model, and is described along with the results in Section 9.9.2. This project scenario shows that even if all pumping were replaced with alternative supplies and pumping was eliminated, the Corral de Tierra Area would still need recharge projects to reach sustainability. The quantification of benefits for decreased extraction are dependent on the degree of pumping reductions or allocations. As the GSP is implemented, these benefits will be further analyzed and quantified based on the actions taken by the GSAs in coordination with other partner entities and local stakeholders.
5. Section 9.3.4 (page 9-18) – In the last para of this Section it mentions that capital costs were annualized over 25 years. The interest rate for this calculation should be stated, and for what revenue source(s) that rate pertains.	Several of the project scenarios have cost explanations in Appendix 9X, and they show their respective, assumed interest rates.
6. Section 9.4.2.2 (page 9-27) – The first sentence of this Section states that 15,000 AFY of desalinated water could be produced for the "Salinas Valley," and the Section goes on to say that a portion of this would go to the Monterey Subbasin. Since the Seaside Subbasin is also part of the Salinas Valley Groundwater Basin, and since this Section is discussing a "Regional Municipal Supply Project," language should be added saying that a portion of the water supply might also go to the Seaside Subbasin which is also in need of a supplemental water source to achieve sustainability.	The text was reworded into "The proposed plant would produce up to 15,000 AFY of desalinated water for the Salinas Valley. A portion of that would go to the Monterey Subbasin, while others would go to other Subbasin within the Salinas Valley Basin." The GSAs would like to focus on Monterey Subbasin in the text.

7. Section 9.4.6 (page 9-51 to 9-54) – This Section discusses the use of recycled water. Thought needs to be given to the limitation on the volume of recycled water that M1W's Salinas Valley Reclamation Plant or its Pure Water Monterey AWT Plant can produce. The feedwater source for both of those plants is M1W's Regional Treatment Plant, and its flow is currently only about 19 MGD. Water conservation and other factors have nearly eliminated increases in wastewater flows to that plant in recent years. With the CSIP being proposed for expansion in the 180/400-foot Aquifer Subbasin's GSP, with a Pure Water Monterey Expansion Project being proposed for the Seaside Subbasin, and now with the Monterey Subbasin GSP proposing obtaining recycled water from M1W, there appears to be a real risk that the amount of recycled water that can be produced may be over-subscribed.	As described on page 9-53, first paragraph, "MCWD's sewer flows will increase over time as MCWD's water demand increases and could be used as source water for a MCWD expansion of the AWPF." The indirect potable use (IPR) option of this project includes a proposed expansion to the M1W Advanced Treatment Purification Facility that could utilize future sewer flow generated by MCWD.
8. Section 9.4.6 (page 9-52) – The PWM Project currently is only sized to deliver 3,500 AFY to the Seaside Subbasin, not 3,700 AFY as stated in the 4th para on this page. Also on this page it states that the AWPF will be expanded. The word "may" should be used in lieu of the word "will" as there are still obstacles to the proposed expansion project.	Clarification added. The AWTF and regional transmission pipeline was constructed with a capacity of 3,700 AFY for the PWM project to deliver 3,500 AFY to the Seaside Subbasin.
9. Section 9.4.6 (page 9-53 to 9-54) – On these pages it mentions "a MCWD expansion of the AWPF." That should read "a M1W expansion of the AWPF."	Updated.
10. Section 9.4.6 (page 9-54) – The last para in this Section on this page starts out with "The current operation frequency of MCWD's productions generally ranges from 10% to 40%." Please clarify what this statement means.	Text was updated to "The current operation frequency of MCWD's production wells generally ranges from 10% to 40% (i.e., these wells are being operated 10% to 40% of the time)."
11. Figure 9-7 – The RUWAP pipeline is shown extending down General Jim Moore Boulevard clear through Del Rey Oaks and then easterly into Ryan Ranch. Please verify that this pipeline has already been constructed that far. I was of the understanding that it only went part of the way down General Jim Moore and not even as far as South Boundary Road.	The pipeline extends to near South Boundary Road in GJMB but is not constructed within South Boundary Road (the portion that heads east at the southern part of the diagram). The extension of the recycled line down South Boundary road is planned but not yet constructed.

12. Section 9.4.8 (page 9-65) – The para in the middle of this page states in part "…if pumping needs to be reduced to meet sustainable yield…". It is not "if" but simply "will" need to be reduced. Calculations in earlier GSP chapters identify the estimated sustainable yield, and the amount of overpumping that will have to be eliminated to achieve sustainable yield. In addition, sustainability will also necessitate raising groundwater levels in this Subbasin, not just having extractions equal natural replenishment. The reader should clearly be informed that pumping reductions will be necessary, and not misled into thinking that somehow the other Management Actions and Projects will achieve sustainability. In this Section (or elsewhere in this Chapter) there should be a discussion of how users will be able to achieve the necessary level of pumping reduction and still meet the water demands of their customers. This is a problem already being faced in the Seaside Subbasin, specifically with the City of Seaside's Municipal Water System. That System's only source of water is groundwater from the Seaside Subbasin. If further pumping reductions affecting that Water System were to be imposed, it would be unable to supply its customers water needs.	Text described this type of allocation structure, not the current conditions of the Corral. However, to address the comment text has been edited to say "To reduce pumping to meet the sustainable yield, all users would reduce water usage by the same percentage, except for de minimis users." Even though this is a preferred method to reach sustainability, since it is only one of the options for reaching sustainability, this is not the place to discuss the necessity of pumping reductions. A section has been added to the end of Chapter 9 that discusses project scenarios with modeling to assess the need to meet sustainable yield requirements for the Subbasin. Within this section, the following text has been added that specifically addresses this comment: "This project scenario shows that even if all pumping were replaced with alternative supplies and pumping was eliminated, the Corral de Tierra Area would still need recharge projects to reach sustainability."
13. Section 9.4.8 (page 9-65) – In the bottom para on this page it states in part "If the sustainable yield is lower than current extraction…". Earlier chapters in this GSP have clearly shown that current extractions exceed the estimated sustainable yield. So it is not "if" the sustainable yield is lower than current extraction. This sentence should be rewritten to correct this misstatement, and to not leave the reader with the impression that pumping reductions may not be necessary.	See response to Comment 12.
14. Section 9.4.8.2 (page 9-66) – The second para in this Section states that the network of monitoring wells is monitored by MCWRA. The Seaside Basin also monitors wells which my earlier comments (on Chapter 8) recommended be included in the monitoring well network for the Corral de Tierra Subbasin. Language should be added here to point this out.	MCWD GSA and SVBGSA will include monitoring data from Seaside Subbasin in the future annual reporting as appropriate. Since similar language has been added to Chapter 8, the GSAs intend to focus on Monterey Subbasin in Chapter 9.

15. Section 9.4.8.8 (page 9-67) – The word "Subbasin" is missing after the word "Monterey" in the first sentence of the para at the bottom of this page.	Update has been made.
16. Section 9.4.9 (page 9-68) – I commented at one of the earlier GSP Committee meetings that any reduction in flows in any of the creeks in the Corral de Tierra Subbasin that flow westward toward the Seaside Subbasin might reduce the natural replenishment of the Seaside Subbasin. This needs to be pointed out in this Section, and that a hydrogeological evaluation of the impacts of any such projects be prepared to determine if such reductions would adversely impact the Seaside Subbasin.	There is currently no knowledge of westward flowing creeks from the Corral de Tierra Area towards the Laguna Seca area. The Canyon Del Rey watershed overlaps small portions of the western edge of the Corral de Tierra area, however previous reports indicate the majority of the runoff that may occur in this watershed come from the southern boundary of the watershed, south of Highway 68. Additionally, previous reports indicate this watershed has high infiltration of precipitation due to soils composition. During implementation, as data are collected, more analysis will be included to determine surface water relationships between the Corral de Tierra Area and the Laguna Seca area.
17. Section 9.4.11 (page 9-78) – The second sentence in this Section on this page states in part "This water will be disinfected tertiary levels…". It would be clearer and more correctly stated that "This water will be treated to a tertiary level…".	Update has been made.
18. Section 9.5.6 (page 9-102) – The last sentence in the first para on this page mentions effects on groundwater levels in the Monterey Subbasin. Wording should be added to this sentence that effects on groundwater levels in the adjacent Seaside Subbasin should also be evaluated using this model.	Text was updated to "It is anticipated that this model may be expanded to include the coastal area of the 180/400 Foot Subbasin and will aid in evaluating the potential effects of regional projects on seawater intrusion and groundwater levels in the Monterey Subbasin and adjacent subbasins including Seaside and 180/400 Foot Aquifer Subbasins."

19. Section 9.5.7 (page 9-103) – This Section includes a statement that "SGMA does not allow metering of de minimis well users…". SGMA Section 5202 states that the requirement to file an annual report of groundwater extraction does not apply to de minimis extractors. It says nothing about "not allowing metering", nor does it say anything that would prevent a jurisdiction, such as Monterey County or the Monterey County Water Resources Agency, from imposing such a reporting requirement separate from the requirements of SGMA. This language should be corrected to more accurately state what SGMA says. Section 10730(a) of SGMA states in part "A groundwater sustainability agency shall not impose a fee…on a de minimis extractor unless the agency has regulated the users pursuant to this part." It is not clear to me what "regulated the users pursuant to this part" means. It would be good to have a legal review made of the issue of imposing a requirement for de minimis extractors to file annual extraction reports to see if such reporting could be required and not be in conflict with SGMA. This could be very helpful in managing the Subbasin, since there are so many de minimis extractors.	~~The SVBGSA will solicit further legal advice early during GSP implementation and potentially partner with MCWRA and/or the County on addressing *de minimis* extraction.~~ A GSA may not require de minimis users (as defined) to meter or otherwise report annual extraction data. Other public agencies such as the County or Water Resources Agency may have such authority. SGMA allows a GSA to implement regulations to achieve sustainability, including the regulation of extractions, even from de minimis users. If the GSA implements such regulations applicable to de minimis users, it can charge a fee to the de minimis user if the fee is imposed as required by SGMA. The SVBGSA will consult with the County and the Water Resources Agency on addressing the issue of reporting by de minimis users, as they each may have such authority.

Draft Chapter 6 – Comments from Seaside Basin Watermaster 9-6-21

Comments	Responses
1. Section 6 – Just above the bullet list on this page it states there are Three budget time periods, however the chart below the bullet list shows Four time periods. I did not see the value of showing the "Historical Model" bar in the chart since it seemed like only the 15-Year Historical bar was used. Also, I did not understand footnote number 2 on this page – please clarify what is meant by a "five-year equilibration period".	Please see the footnote below the bar chart for details. The five-year equilibration period (WY 1998-2003) allows the model to stabilize from initial conditions, prior to simulations during the 15-year historical period (WY 2004-2018). Please see Section 6.1 for the model calibration discussion.
2. Section 6.1 – The last bullet on this page discusses pumping from various wells. Wouldn't pumping from wells in the Seaside Basin affect ground water levels, and therefore need to be included in the MBGWFM due to the hydrogeologic interconnection between the Seaside Basin and both subareas of the Monterey Subbasin?	The current MBGWFM does not expand to the Seaside Subbasin; however, the boundary condition should have captured the effects of pumping in the Seaside Subbasin. MCWD will continue to with the Seaside Basin to further rectify the discrepancies between the two models in a future update to the MBGWFM, and/or to integrate both models into a regional model that covers both subbasins.
3. Section 6.1.1 – Same comment as on page 6-10 (Comment 2) pertaining to <u>Pumping Records</u>.	See response in Comment 2.
4. Section 6.2.2 – Same comment as on page 6-10 (Comment 2) pertaining to <u>Groundwater pumping</u>.	See response in Comment 2.
5. Section 6.3.3 – Don't understand why there are three bullets shown on this page with each bullet saying the same thing.	The three "analog periods" were created from 20 years-worth of historical information (WY 1999-2018), which maintained the long-term average hydrologic conditions on average. The first two periods, analog years 1-20 and 21-40, repeats hydrology of actual years 1999-2018; while the third period, analog years 41-50, repeats hydrology of the 10-year period 1999-2008.
6. Table 6-1 – Footnote (a) would be good to add to each of the tables in the Appendix in which water budgets are shown, to clarify what a positive or negative value means.	Updated

7. Figures 6-4 to 6-6, and Tables 6-4, 6-6, and 6-7 – Under future anticipated pumping conditions, the outflow from the Corral de Tierra subarea into the Laguna Seca Subarea of the Seaside Subbasin shown in these Figures and discussed in these Sections is projected to start reversing in the future as groundwater levels in the Corral de Tierra continue to fall. The reversal would result in water starting to flow out of the Laguna Seca Subarea and into the Corral de Tierra subarea. This was the finding of Watermaster modeling performed by HydroMetrics in 2016 in their Technical Memorandum dated January 27, 2016 titled "Groundwater Flow Divides within and East of the Laguna Seca Subarea." That report is contained in Attachment 12 of the Watermaster's 2016 Annual Report which can be viewed and downloaded at this URL: http://www.seasidebasinwatermaster.org/Other/2016%20 Final%20Annual%20Report%2012-8-16a.pdf. This should be discussed and addressed in Chapter 6 of the GSP.	Seaside, MCWDGSA, and SVBGSA modelers have begun collaborating to collaborate to improve the understanding of the relationship between Laguna Seca and the Corral de Tierra. The modeling performed by HydroMetrics in 2016 has a different set of assumptions and boundary conditions than the modeling performed by EKI. The MBGWFM does not show that the groundwater flow will reverse and flow out of the Laguna Seca area under future conditions. These models will be revised through a series of meetings with the modelers to better align assumptions, boundary conditions, and predictions over time.
8. Section 6.4.1.1.2 – In the 2nd para of this Section the typo "and" should be corrected to read "an."	Updated
9. Section 6.4.1.1.3 – In the upper bullet of the group of bullets in the center of this page it mentions an inflow from the Seaside Subbasin into the Monterey Subbasin, the majority of which is between the Seaside Subbasin and the Marina-Ord subarea of the Monterey Subbasin. There is a flow divide between that subarea and the Seaside Subbasin which I understood would prevent this. That should be discussed in this Section. This comment also pertains to Table 6-2, Also in this same para the typo "and" should be corrected to read "an."	The magnitude of inflow from the Seaside Subbasin into the Monterey Subbasin is consistent with prior water budgets prepared for the Seaside Subbasin, such as those presented in CH2M (2004) and Yates (2005). As discussed in 6.2.2, this inflow is calculated by the MBGWFM based on modeled groundwater head outputs at the Seaside boundary from the historical Seaside Basin Groundwater Flow Model (Hydrometrics 2009 & 2018) and lateral hydraulic conductivities at boundary cells. Typo had been corrected.

10. Section 6.4.3.1.2 – In this Section there are typos in the 3rd sentence which does not make sense. The statement in this Section regarding a significant amount of pumping data being missing because *de minimis* pumpers do not have to report pumping data provides support to my comment made on the Comment website and at the August 25th GSP Committee meeting that a legal look should be made into whether/how *de minimis* pumping reporting could be required.	The SVBGSA will partner with MCWRA to develop a plan to address *de minimis* extraction.
11. Section 6.5.2.2 – An explanation is warranted regarding the statement in this Section that "No project scenarios were run for the Corral de Tierra area at this time."	Since this comment, a 'project' scenario was run for the Corral de Tierra and added to Section 9.9, as it relates to projects and management actions.
12. Section 6.5.3 – The top para on this page discusses the potential for expansion of the seawater intrusion front in the Monterey Subbasin. This should be considered a significant concern and should be discussed in the Plan Implementation Chapter 10.	This paragraph discusses that change in the magnitude or direction of inter-basin flows could cause expansion of the seawater intrusion front in the Monterey Subbasin. Therefore, MCWD GSA has established a set of wells to monitor the protective groundwater gradient as described in Section 7.3.3. Section 10.2.4.2 states "Spatial data gaps within the seawater intrusion monitoring network in the Marina-Ord Area are located in the same general area as the data gaps identified within the groundwater elevation network. Therefore, the aforementioned new monitoring wells to be constructed in the Marina-Ord Area will be monitored for both groundwater elevation and seawater intrusion." The GSAs plan to monitor seawater intrusion closely by installing monitoring wells, gathering water quality data, and completing an annual report.
13. Section 6.5.5 – In the 1st sentence of the 2nd para of this Section the word "scenario" should be inserted after the word "project."	Updated.

14. Section 6.6.1 – I concur with the discussion on this page that "…simply reducing pumping to within sustainable yield is not proof of sustainability under SGMA, which must be demonstrated by avoiding undesirable results for all 6 sustainability indicators." I also agree with the statement at the bottom of this page that "…confirmation that these quantities could be extracted without inducing seawater intrusion has to be verified." To augment this discussion it would be good to add some language explaining that in order to prevent inducing seawater intrusion, ground water levels near the coast need to be at or above protective elevations. This may necessitate replenishing a basin in order to raise its groundwater levels, not just pumping at the estimated sustainable yield level to stabilize groundwater levels if they would still be below sea level.	The groundwater elevation MTs are set at historic groundwater elevation in the intruded 180-Foot and 400-Foot Aquifers as there has been no observed expansion of the seawater intrusion front over the historical period. This criteria is consistent with the Minimum Thresholds established for the 180/400-Foot Aquifer Subbasin, where a seawater intrusion barrier is considered. In the absence of an injection/extraction barrier, groundwater elevation may need to raise to seawater protective levels to stop further seawater intrusion and meet Measurable Thresholds for seawater intrusion. The basin GSAs will continue to monitor seawater intrusion and fill data gaps in the seawater intrusion monitoring network. In the event that monitoring indicates expansion of the seawater intrusion front, local projects such as IPR could be implemented to raise water levels in selected areas through injection of recycled water (i.e., IPR project) or in lieu recharge as identified in Chapter 9. In the event that monitoring data indicate rapid vertical downward migration of the seawater intrusion front, SMCs may be adjusted to address this issue. Annual and 5 year reports required under SGMA will be used to identify such changes if required.

15. Section 6.6.2 – I concur with the discussion on this page that "…simply reducing pumping to within sustainable yield is not proof of sustainability under SGMA, which must be demonstrated by avoiding undesirable results for all 6 sustainability indicators." I also agree with the statement at the bottom of this page that "Further analysis is necessary to refine estimates of where pumping should be reduced to address all sustainability indicators." To augment this discussion it would be good to add some language explaining that in order to enable the adjacent Seaside Subbasin (specifically the Laguna Seca subarea thereof) to achieve sustainability it will be necessary for ground water levels in the Corral de Tierra subarea to be raised, not just stabilized at 2008 levels. This would necessitate replenishing that subarea of the Monterey Subbasin in order to raise its groundwater levels, not just pumping at the estimated sustainable yield level to stabilize groundwater levels.	The long-term sustainability goal is to raise water levels and maintain them to both meet the objectives of the GSP as well as not adversely impact the Seaside Basin. These objectives will be met through a combination of projects and management actions described in Chapter 9.
16. Section 6.7 (Page 6-64) – My comment on page 6-33 also pertains to the discussion in the top bulleted para on this page. Comment on Page 6-33: "In this Section there are typos in the 3rd sentence which does not make sense. The statement in this Section regarding a significant amount of pumping data being missing because *de minimis* pumpers do not have to report pumping data provides support to my comment made on the Comment website and at the August 25th GSP Committee meeting that a legal look should be made into whether/how *de minimis* pumping reporting could be required."	See response to Comment 10.
17. Section 6.7 (Page 6-64) – With regard to the language in the 2nd bulleted para on this page, my understanding is that the Deep Aquifer is not present in the Seaside Subbasin.	The Deep Aquifers are not in the Seaside Basin, but the geologic formations that comprise the Deep Aquifers are present in the Seaside Basin. This bulleted paragraph highlights the differences in the conceptualization of principal aquifers in the Seaside model versus the MBGWFM.

18. Section 6.7 (Page 6-65) – In the next-to-last bulleted para on this page there is mention of monitoring network expansion in the Corral de Tierra subarea. In previous comments I have asked that the monitoring network be expanded to include some of the near-boundary monitoring wells in the Laguna Seca subarea of the Seaside Subbasin. Including those wells should be mentioned in this para.	Laguna Seca wells will be included in the monitoring network, with revised maps being developed post-DWR submittal. They will not be included in the RMS network.

Draft Chapter 10 – Comments from Seaside Basin Watermaster 9-6-21

Comments	Responses
1. Section 10.2 (Page 10-5) – In the 3rd sentence of the top para on page 10-5 the wording "as well" is repeated. In the 3rd para there is discussion of data collection by other agencies. The Seaside Basin Watermaster should also be listed as it collects monitoring well data that will be useful.	These two comments were addressed.
2. Section 10.2.2 (Page 10-6) – In the 2nd para of this Section there is discussion of data collection by other agencies. MPWMD and the Seaside Basin Watermaster should also be listed as they collect monitoring well data that will be useful.	Updated.
3. Section 10.2.4.5 – There is the statement in this Section that "…monitoring wells outside the Monterey Subbasin cannot be included in the Subbasin's monitoring well network…" I believe thisis an incorrect statement. I could find no such prohibition anywhere in SGMA. Also in this Section there is discussion regarding monitoring well FO-9 shallow. That language should be edited to read as follows: *Within the Seaside Subbasin, ~~the Watermaster is proposing to replace~~ monitoring well FO-09 Shallow where casing leakage has been identified is likely to be replaced. The monitoring well is located nearthe coastline just south of the Seaside-Monterey Subbasin boundary. It is used to (a) monitor groundwater levels relative to seawater intrusion protective groundwater elevations and (b) monitor ~~chloride concentrations~~ water quality in groundwater to detect occurrences of seawater intrusion into both Subbasins*	Per the DWR document (Draft Best management Practices for the Sustainable Management of Groundwater – Sustainable Management Criteria Dated November 2017), "Representative monitoring sites are a subset of a basin's complete monitoring network, where minimum thresholds, measurable objectives, and interim milestones are set." Thus, only wells within the Monterey Subbasins are selected for RMS wells. This section has been edited accordingly.
4. Section 10.2.5 (Page 10-10) – In the next-to-last bullet on this page the word "the" should be inserted before the word "boundary."	Updated
5. Section 10.3 (Page 10-11) – In the first para of this Section "the Seaside Basin Watermaster" should be inserted just before the word "other."	Rephrased it to state "In addition, the basin GSAs have and will continue to coordinate with other entities (including the Seaside Basin Watermaster) on water management efforts that involve the larger Salinas Valley Basin."

6. Section 10.5 (Page 10-12) – At the end of the 3rd para in this Section the words "and the Seaside Basin Watermaster's Seaside Basin Model" should be added. In the 4th para in this Section please clarify what is meant by the words "standing up" as it pertains to the Dry Well Notification System.	Updated. It is a typo which has been corrected.
7. Table 10-1 – My comment on page 10-9 about including monitoring wells outside of the Monterey Subbasin seems to be addressed in the line-item titled "Voluntary monitoring of non-RMS wells." Please clarify in the text if that is correct.	This item, as described in the "Assumptions" column, primarily includes specific conductivity monitoring of non-RMS monitoring wells within the Subbasin. However, as described in Section 10.2.4.5, the Seaside monitoring wells will be included in the monitoring network and will inform future SGMA-related analyses.
8. Table 10-1 – In the line-item titled "Improving Monitoring Networks" the same language that is contained in Table 10-2 on page 10-21 "Add Seaside Subbasin wells to monitoring GWL network" should be added.	See response to Comment 7.
9. Figure 10-1 – Is there a statutory allowance of 2 years for DWR to review GSPs? This seems inordinately long and could cause problems for the GSAs if DWR took that look to provide its feedback.	Yes, the DWR has two years to review the submitted GSP. *GSP Regulations Sec 355.2(e) The Department shall evaluate a Plan within two years of its submittal date and issue a written assessment of the Plan, which shall be posted on the Department's website.*

Appendix 2-F

SVBGSA Subbasin Committee Comment Table

COMMENTS RECEIVED FROM JULY 7, 2020 to December 13, 2021										
Number	**Chapter**	**Table**	**Page**	**Figure**	**Comment Type**	**Date**	Commenter	**Comment**	Response	**Action**
1					Meeting	7/7/2020	Bob Jaques	Will you please say something about Seaside Subbasin?	Emily: Yes, the other 6 generally fall under the SVBGSA jurisdiction. Seaside does not because it is adjudicated.	Meeting comment - noted.
2					Meeting	7/7/2020	Bob Jaques	When do you anticipate releasing the initial set of draft chapters?	Emily: As soon as we're ready. We are reviewing and will release them as soon as humanly possible.	Meeting comment - noted.
3					Meeting	7/7/2020	Janet Brennan	Will those elements you mention be a part of each GSP? So we will be looking to do something similar as the 180/400?	Emily: Yes	Meeting comment - noted.
4					Meeting	7/7/2020	Sarah Hardgrave	With respect to the chapters and topics, given that we're coordinating with MCWD, will there be a single description of the plan area and the HCM? Or will there be two separate descriptions?	Emily: I will defer to Derrik Williams. We are still figuring out how to put this together. We will end up with one GSP, but how the chapters will look is yet to be determined. DW: As Emily points out, we will write one GSP, so the description will be for one basin. If we decide on management areas, there will be those descriptions. However, these additional descriptions need to add up to one basin. I went over the regulations this morning, and we're still working this out.	Meeting comment - noted.
5					Meeting	7/7/2020	Sarah Hardgrave	Patrick will you have separate stakeholder engagement outreach? Will we be	Patrick Breen: We are planning on having separate stakeholder meetings for the Marina-Ord area, and we will send out notice soon. Patrick: It will be a separate group, but it will be a public meeting so everyone here is welcome to join. We are working it out this month. Donna: We are working under a framework agreement. We have our own process, but we are very much coordinating and working under the framework agreement.	Meeting comment - noted.
6					Meeting	7/7/2020	Sarah Hardgrave	Is that framework agreement posted?	We can send it to the subcommittee	Meeting comment - noted.
7					Meeting	7/7/2020	John Farrow	I was interested in hearing about the coordination with MCWD. I think the framework agreement should be posted for the public to view.		Meeting comment - noted.
8					Meeting	7/7/2020	Bob Jaques	I think it would be important to include the Seaside Model developed by HydroMetrics, in addition to the SVIHM and SVOM listed.		Meeting comment - noted.
9					Meeting	7/7/2020	Sarah Hardgrave	Are these workshops meant to be for all subbasins?	Emily: Yes they are. Bob, we have talked about your suggestion. We are planning for the Monterey Subbasin to have a specific Seaside meeting, possibly early in the process (Aug, Sept). Could we cover the model in that meeting? Bob: I think that's a good idea, and I'd like to make a presentation. I spoke with M&A, September is looking good and I think it would fit in well with GSP development. Sarah H: I think that's a good plan.	Meeting comment - noted.
10					Meeting	7/7/2020	Jon Farrow	First, want to make sure there's an opportunity for comment on the drafts; I assume you will proceed similar to 180/400 and post the chapters on the website. 2nd, I'm interested in how you'll coordinate with 180/400 subbasin. Coordination with projects and water charges framework. Not clear to me how that coordination will work out, especially with the integrated plan. Third, you mentioned there would be an opportunity for this committee to provide steering on the drafts before the drafts are written. The SMCs presentation describes options, but how to pick which option will be more suitable. I see the recommendations are not planned for September, but you won't in fact be seeking guidance or in the workshop later this month, on how to focus on one option or another. Those options need to be informed by data and information which is not available yet.	Emily: As the draft chapters are available, they will be included in the agenda packets and posted on the website. They will be very accessible. To the third question about when we will seek input, it's scheduled for September, but we can push it depending on if we're ready. Today is mainly informational. Donna: We will be tracking all the subbasin planning efforts against the 180/400. The 180/400 is kind of the foundational GSP, and was required by the state to be completed first due to its condition. The ISP committee will be looking at the technical aspects of each GSP to see how they will work. The SWIG had its first meeting this month, filled with technical experts and various agencies and groups. The SWIG is looking at developing agreement and how to define SWI and conditions. As we move through the planning process we will look at the integrative parts as well. This integrative planning will be more available at the Adv Committee and BOD meetings.	Meeting comment - noted.
11					Meeting	7/7/2020	Janet Brennan	It was recommended that we use a consensus process to make decisions for the GSP plans. This is a different process than what we used in the 180/400. Can you explain this?	Emily: This process of finding consensus is what Gary intended as well, since I used his slides. What we'll be asking for is strategic direction. The board will look at accepting the plan. We need strategic direction from you.	Meeting comment - noted.
12					Meeting	7/7/2020	Sarah Hardgrave	You did identify we would be making motions and taking votes. There is a goal to achieve consensus, but we will be making motions and taking votes also?	Emily: Exactly. If there is a wide variety of opinions, we'll document that too.	Meeting comment - noted.
13					Meeting	7/7/2020	Janet Brennan	Will each GSP go to the board for approval?	Emily: Our plan is for the comments we receive to be incorporated into the drafts and then go to the board.	Meeting comment - noted.

14					Meeting	7/7/2020	Sarah Hardgrave	With the MCWD agreement, will they have their own committee member for the ISP?	Donna: For the ISP Committee, we would have one represenative from this subbasin committee. The goal is to have one representative from each subbasin. Emily: This is the next agenda item. Within the framework agreement, there are several subcommittees; our committee here, the MCWD committee, a technical committee, a steering committee which will include the GSA manager from each GSA and will provide another layer of alignment to create one GSP. We're looking for one person on this committee to volunteer to be on the ISP and one person for the steering committee	Meeting comment - noted.
15					Meeting	7/7/2020	John Farrow	I have a question about how the technical and steering committees relate to the ISP.	Emily: Technical committee is really to do the work, and make sure the GSP is done in a coordinated fashion with the nuts and bolts of the plan. The steering committee will (as defined in framework agreement) review daft chapters and elevate issues to advisory committee. Any issues to be worked out between the two GSAs will happen here. Donna: To clarify, the genesis of the technical and steering committees really come out of 2018 framework agreement. As each GSA does its work, we wanted to be clear and create as much coordination and communication as possible.	Meeting comment - noted.
16					Meeting	7/7/2020	Gary Peterson	As we think about techical committee, M&A and EKI are meeting to work through technical issues, and the plan is aligned on a technical level. The framework agreement is now 3 years and one GSP old; may be revised. We didn't know what it all would look like when we started it. We can adjust as we go.		Meeting comment - noted.
17					Meeting	7/7/2020	Janet Brennan	I don't understand the hierarchy. Do technical and steering committees provide input? What decisions will these committees be making in relation to how our committee makes recommendations.	Donna: The BOD ultimately has approval over the plan. The technical committee works on technical information, will run through our committee. The technical committee work will come through some of the workshops, and we will discuss these items with you also. Steering committee is related to utilizing BOD member and general managers from each GSA and will keep BOD updated, utilized in slightly different way. ISP Planning committee, fairly clear.	Meeting comment - noted.
18					Meeting	7/7/2020	Janet Brennan	Good overview of recent history. Going back a little bit, seems the Monterey Subbasin used to be a part of the 180/400 subbasin where there is a 3,500 AFY SWI. Why is this subbasin not a part of the 180/400? Why is this subbasin not critically over drafted?	Gary: This is a DWR question. The subbasin determinations were set by DWR.	Meeting comment - noted.
19					Meeting	7/7/2020	Janet Brennan	As part of our subbasin planning, will we address the Deep Aquifer which is a part of this subbasin?	Gary: I would say SWIG will look at that, and it includes City of Marina and MCWD representatives and Bob Jaques, seaside watermaster	Meeting comment - noted.
20					Meeting	7/7/2020	Janet Brennan	Does the Monterey subbasin include all of the Corral de Tierra subbasin?	Leslie Girard: Yes, DWR made corrections to include all of Corral de Tierra.	Meeting comment - noted.
21					Meeting	7/7/2020	Janet Brennan	It seems like there are two distinct subbasin with very different water issues. How are we going to come up with single criteria for the subbasin? Are we going to come up with separate criteria for separate areas?	DW: The criteria, depends on which you're talking about, will be set differently for different areas. However, they must tell a single integrated story. The can be separate, but have to be coordinated. Storage is an example of a single basin criteria. One area cannot prevent another area from reaching sustainability.	Meeting comment - noted.
22					Meeting	7/7/2020	Janet Brennan	That suggests that the area with the greatest problem will be the one that sets the standard.	DW: Not necessarily. It comes down to negotiation between the areas. What is significant and unreasonable in each area. What is a future condition we can reasonably achieve.	Meeting comment - noted.
23					Meeting	7/7/2020	Margaret Anne	Very impressed with the job you've all been doing.		Meeting comment - noted.
24					Meeting	7/7/2020	John Farrow	Not clear if there will be a single GSP to cover both areas. Will it be drafted by this committee or MCWD or the BOD? Do all GSAs need to approve the GSP? Are the jurisdictional areas where they have annexed? Or where there services areas are? Seems to have been given large area. I'm wondering if MCWD representative sought the boundary changes and not DWR, could the MCWD representative give more background? Seems like it has created a complex problem with coordination and the SWIG.	Gary: [map] the green areas are the expanded annexed areas. On left, corral de tierra area. The Ord area in the middle. Leslie Girard: Under SGMA the jurisdictional boundaries of MCWD are its boundaries. That means a GSA cannot impose fees on areas outside of those boundaries. They are service provider for much of the area outside of their jurisdictional boundary. They cannot impose a fee outside of their jurisdictional boundary. DWR allowed for management outside their jurisdictional boundary (MCWD) and SVBGSA will manage the corral area. Patrick Breen: Have nothing to add. We will work together as Leslie Girard described.	Meeting comment - noted.

25					Meeting	7/7/2020	Sarah Hardgrave	Special request for special meeting to have discussion about the edges of the Monterey subbasin. Especially with respect to Laguna Seca area and impact to Seaside, and how SMC apply to adjacent subbasins and coordination actions with neighboring subbasins, like 180/400 subbasin.	DW: Happy to add that in.	Meeting comment - noted.
26					Special Meeting	7/17/2020	Sarah Hardgrave	Is subsidence data reflecting only groundwater impacts, or other sources of change?	DW: Yes. Possibly seeing subsidence due to faults in the area. InSAR data is satellite data, if you till field and move land surface, will show up on InSAR. We will add caveats to text, and explain must be due to lowering groundwater levels.	Meeting comment - noted.
27					Special Meeting	7/17/2020	Janet Brennan	It seems like it would be helpful to have the same subsidence [SMC] as the 180/400.	DW: Great point, SGMA requires us to not cause adverse effects to our neighbors. If we say, can allow 8in drop and they say 0in drop, they can say 'you are preventing us from reaching sustainability.' This is my opinion, if subsidence is not a problem for you, choose 'subsidence is 0 subsidence. There's a right answer and a wrong answer. Yes the 180/400 is zero subsidence.	Meeting comment - noted.
28					Special Meeting	7/17/2020	Janet Brennan	Lacking data, do we have the possibility of simulation?	DW: I suppose the question is really, how accurate are the simulations? They will probably have used that USGS gage for part of the simulation. Make assumptions that the data is 'good enough'. There will be uncertainty, and we can talk about that uncertainty. We can incorporate the uncertainty by including conservative approaches to depletion, or shallow GW levels.	Meeting comment - noted.
29					Special Meeting	7/17/2020	Janet Brennan	Doesn't GDE and ISW require monitoring?	DW: SGMA discusses the rate of depletion, not the flow in a stream or level in a lake. We're measuring our *impact* on SW bodies through GW management.	Meeting comment - noted.
30					Special Meeting	7/17/2020	Janet Brennan	I don't understand how you can do that without being able to measure your impact.	DW: I'll go over more what we did in the 180/400, and talk about some recommended approaches. What we're looking at, historically, has our pumping cause an undesirable effect on the SW? The easiest one to understand is, is there a flow requirement for fish in the river? Has the current rate of pumping caused you to fail to meet that flow requirement? This is about meeting legal obligations with current rates on depletion. This is not the same as knowing what the flow is at any given time.	Meeting comment - noted.
31					Special Meeting	7/17/2020	Sarah Hardgrave	Regarding the model, how it is designed, especially with respect to the relationship between SW and GW. I think a lot of these are intermittent streams which flow during the rainy season. Does the model account for that kind of input from streamflows?	DW: Yes it does. The model has a series of stream inputs. Since it is a GW model, the stream inputs are a little rougher than if this was a stream model.	Meeting comment - noted.
32					Special Meeting	7/17/2020	Sarah Hardgrave	Does it estimate the quantities for different size storm events?	DW: Not in the GW model, but there is a watershed model that is able to estimate runoff. There is a tool that can feed into this and estimate runoff from storms.	Meeting comment - noted.
33					Special Meeting	7/17/2020	Sarah Hardgrave	Can you explain how much water is expected to be in a stream?	DW: For the calibrated period, a period of time where we have data, those data will be in the model. We can say, ok it's doing a reasonable job of estimating the amount of water in the stream. So when they simulate future scenarios, they will be able to say if it's a reasonable estimate. The question is, how important is El Toro creek with connection to GW. This is something we'll be looking for feedback on. Is this really driving sustainability or not. We could say, current conditions are unreasonable or not? El Toro creek may be a good one to look at due to less stratification to aquifers.	Meeting comment - noted.
34					Special Meeting	7/17/2020	Margaret Ann Copernall	Are going to consider the impact on Sea Water Rise?	DW: I will get into it in 3 metrics. Sea Level Rise is an interesting question, and I'll come back to that with sea water intrusion.	Meeting comment - noted.
35					Special Meeting	7/17/2020	Harold Wolgamott	How are we going to write a caveat? This is depletion of GW level. If there is no GW level, we can't control precipitation, how to we write a caveat to explain that?	DW: I don't know if we do write caveats for GW levels? One of the questions that come up is about when there is a drought? The point of these metrics is we are managing a 50yr plan, long-term averages, towards an objective. We try to account for droughts. DWR understands there will be droughts, and people will fall off their plans. We can write a drought caveat.	Meeting comment - noted.
36					Special Meeting	7/17/2020	Bab Jaques	You mention if there's a lack of data on GW levels in the Corral area, ideally, even before you establish the SMC, you would want to obtain more data. I don't know if there's time during GSP development to do that, or if you will be using Seaside Model data. What would be the most effective way to handle that?	DW: You're getting to an important distinction. If we say GW levels in 2015 are significant and unreasonable. We can look at what wells we have, set our SMCs there, then say, we don't have enough wells. During implementation, we can look for more wells. Before we have all data, we will set what we consider significant and unreasonable. We can find new monitoring wells in the future.	Meeting comment - noted.

37					Special Meeting	7/17/2020	Bob Jaques	I understand the GSA received grant money to develop GSP. Can some of that money be used for looking for data?	DW: Ms. Gardner would know more Emily: You do have to have a good grasp on where your data gaps occur so you can provide the missing information. You don't have to have submitted the GSP, but far enough in the process to know where you don't have data	Meeting comment - noted.
38					Special Meeting	7/17/2020	Janet Brennan	I assume, based on the relationship to domestic wells, 1ft above 2015 levels, accounts for these criteria. They are not mutually exclusive. The GDEs, the domestic well issue, we should be able to address these with one threshold. The relationship of GW levels 1ft above the 2015 levels, whether or not that is consistent with Seawater Intrustion concerns.	DW: two good questions. First, you're correct, these options are not mutually exclusive, and you can set the SMCs that way. You can combine the ideas of GDE and groundwater levels. Second, for Seawater Intrustion, there are a couple ways to look at this. Each of the SGMA 6 sustainability indicators, we have to avoid undesirable results simultaneously. No matter what we say, we have to stop SWI. If we don't use GW elevations to stop SWI, that's ok, find another way. You can define everything separately. Some people have tried to address everything all together, stitched together with a GW elevation map. It kind of assumes you already know your projects and actions ahead of time. You have SGMA 6 undesirable results to avoid simultaneously. You can be well above your GW elevation mininimum thresholds for SWI, and meet both.	Meeting comment - noted.
39					Special Meeting	7/17/2020	Janet Brennan	Because our approach to Seawater Intrusion is more to stop the Seawater Intrustion and not related to Groundwater levels, are they compatible?	DW: Say there are two ways to approach this: raise all GW levels and push it back, or drill wells and draw the water down. We may not want to predicate it all together. Things can change in the future. It is a complicated topic.	Meeting comment - noted.
40					Special Meeting	7/17/2020	Sarah Hardgrave	Do we have data in the Corral subarea in terms of the number of wells and kinds of wells they are? I understand domestic wells serving 1-2 households are not regulated, considered de minimis under the law. I understand these wells are the primary types of wells in the Corral area. Can the de minimis users be considered cumulative?	DW: You are correct, we have some data from the Corral area. I will point out we are missing some data from this area. It is a data gap we have to fill, and it will cause us a problem to implement a threshold. You're right, any well that serves a household, no crop, less than 2AFY, de minimis. We cannot force domestic well owners to report to pumping to the GSA or to DWR. I believe we can include them in the management structure, both individually and collectively, but I don't know how just yet. Marina P: We can ask Les Girard to help clarify.	Meeting comment - noted.
41	`				Special Meeting	7/17/2020	Sarah Hardgrave	Without understanding the number of wells, their depths, and how much they're pumping, it seems hard to manage. I am aware for the CALAM managed systems, Ambler and Toro, they have a water quality question with regard to arsenic.	DW: Yes good to know that it should be one of the drivers of our groundwater elevations.	Meeting comment - noted.
42					Special Meeting	7/17/2020	Janet Brennan	I assume this does not address the deep aquifer?	DW: It will include the deep aquifer. It doesn't show up in the whole basin. If we set the total pumping, it will include the Deep aquifer.	Meeting comment - noted.
43					Special Meeting	7/17/2020	Janet Brennan	How did we address it in the 180/400?	DW: We do not set this aquifer by aquifer, we address it as a whole basin. So, this will include the deep aquifer.	Meeting comment - noted.
44					Special Meeting	7/17/2020	Sarah Hardgrave	Because the SWI is occuring in the MCWD management area, what roll does this committee play in working with MCWD in setting this SMC? Will we have the opprtunity to weigh in? Will that be done solely by MCWD then negotiated?	DW: There is a good working relationship right now between the GSAs. The decision-making details have not been worked out. We will continue working coooperatively.	Meeting comment - noted.
45					Special Meeting	7/17/2020	Beverly Bean	I was under the impression that MCWD has already written a GSP and when can we see it?	DW: We are writing a single GSP with EKI.	Meeting comment - noted.
46					Special Meeting	7/17/2020	Beverly Bean	Does their GSP cover the 400 acres?	Gary: The City of Marina has written their GSP. We have read it and commented.	Meeting comment - noted.
47					Special Meeting	7/17/2020	Beverly Bean	Will we be looking at that plan as this committee moves forward? I suggest we look at it to incorporate all available input.	Gary: Derrik is well aware of the plan	Meeting comment - noted.
48					Special Meeting	7/17/2020	Beverly Bean	Is our GSP to replace the plan that Marina wrote?	Sarah: I don't believe so, that area is not in our subbasin. It's in the 180/400 DW: We are not replacing their GSP, it's not in this subbasin Gary: That plan was for an area within the 180/400 subbasin and does not impact our subbasin or GSP	Meeting comment - noted.
49					Special Meeting	7/17/2020	Tamara Voss	I'm with MCWRA, and I'm with group that creates the SWI maps. The area to the south in both the 180' and 400' SWI maps are areas where there is a large data gap. We put a gray band with black question marks to denote the missing data on our maps. I want to make sure everyone knows this is an area with missing data.		Meeting comment - noted.
50					Special Meeting	7/17/2020	Tina Wang	I want to tack on, there is a limited number of wells along the coast for data. There are the sentinel wells put in by the Seaside watermaster and we will look in to those wells.		Meeting comment - noted.

51					Special Meeting	7/17/2020	Bob Jaques	The Salinas Valley Integrated model is going to be used for modeling purposes for all Salinas Valley GSPs. How will that be coordinated with the Seaside GW Model, especially with respect to the Corral area? Do you envision any model runs during Corral GSP developmetn? Or will that be after the GSP approval and implementation.	DW: I believe the USGS has the Seaside model and will incorporate it. There may not be significant differences, but we'll have to negotiate out the differences if they are important. We will run the model during development, several simulations to work out projects and actions.	Meeting comment - noted.
52					Special Meeting	7/17/2020	Sarah Hardgrave	I observed a discussion of the Seaside watermaster and the area where there is a data gap along Fort Ord and to the Coast. I would like to have a conversation about how the monitoring network can be expanded because I don't think we can rely on existing data.		Meeting comment - noted.
53	3	Table 3-2 Existing Well Types			JotForm	7/16/2020	Heather Lukacs	We request that this table include all Monterey County regulated drinking water systems and clearly distinguish between type of drinking water system. Local small water systems serve 2-4 connections, state small water systems serve 5-14 connections, private domestic wells serve 1 connection. In addition this table should list agricultural and industrial users as separate well types. This distinction is made in Figure 3-6 but not in this Table. It is important to distinguish between well type here in order to set the stage for good water budget estimates, for the monitoring network, and throughout the plan. This data is all readily available to the public and GSA.	Submission Received	Table 3-2 was made using DWR's OSWCR database, and it does not provide information on the amount of agricultural and industrial wells so these categories have to be combined into the production category. The parcel data used to make Figure 3-6 came from Monterey Country, not from DWR so it is unlikely that these two data sources match up exactly.
58					Meeting	9/4/2020	Beverly Bean	Have any of the recommendations from the GeoSyntec been implemented?	DW: The Zone B8 overlay still only covers the area between the boundary between the subbasins to the Ambler Park area. This overlay says "this is an area of limited water supply". It has not been expanded per the recommendation.	Meeting comment - noted.
59					Meeting	9/4/2020	Beverly Bean	Who would be responsible for implementing those recommendations?	DW: The county planning department would be in charge of the zoning.	Meeting comment - noted.
60					Meeting	9/4/2020	Sarah Hardgrave	Who commission the GeoSyntec report?	Beverly Bean: The County Board of Supes asked for it because of problems with people's wells:	Meeting comment - noted.
61					Meeting	9/4/2020	Janet Brennan	Will the cutbacks in the Seaside Basin be met this year?	Bob Jaques: Yes, through conservation and other measures, they've been able to keep pumping below the 3,000AFY. I anticipate we'll be able to meet that.	Meeting comment - noted.
62					Meeting	9/4/2020	Janet Brennan	CalAm is required to replenish the seaside basin over time. Is that related to the cutbacks?	Bob Jaques: It pays back the basin from the 2007 decision time, by in-lieu replenishment of the basin. By further reducing their pumping by 700 AFY additional, they would pay back what they've pumped since the decision was made.	Meeting comment - noted.
63					Meeting	9/4/2020	Janet Brennan	I think It would be important to know what the demand is in the Corral de Tierra area. That will speak to the kind of projects we need to look at.	DW: We will address that in some upcoming discussions today.	Meeting comment - noted.
64					Meeting	9/4/2020	Sarah Hardgrave	I was involved in the early years of implementation, and have worked with Bob and Derrik. Helpful to see all the work done over time. As you've developed your modeling for the watermaster, can you distinguish the natural safe yield as determined by the court versus the true sustainable yield?	Bob Jaques: Natural safe yield is very simplistic, you look at inputs and outputs at all boundaries. If outputs exceed inputs, you're exceeding the natural safe yield. For sustainable yield, you look at the whole basin. One area can experience drawdown while the whole basin can be sustainable. Our board considered a sustainable yield analysis, but it's very costly. We're waiting to see how the GSP is developed, and then do that analysis with additional information.	Meeting comment - noted.

65					Meeting	9/4/2020	Sarah Hardgrave	Thank you, that is helpful to know. Another observation, the boundaries of the adjudicated area were more political than hydrogeological. The issues between the Eastern Laguna Seca area and the Corral area may be reflective of that. Maybe there isn't a physical division between the subbasins.	Georgina King: You're completely correct, there is no physical boundary there. Parts of the boundary were delineated by flow divides, but we all know those divides change. The boundary shown on the map was actually the incorrect boundary. The correct one was more based on the geology. But yes, you're correct the boundary is more political. DW: Yes, that flow divide was more reflective in the marina area. This corner of the basin was an extension of that line. There really is no difference between managing the Laguna Seca area and managing the Toro/Corral area.	Meeting comment - noted.
66					Meeting	9/4/2020		Subsidence SMC: Motion to accept Option 1: Any subsidence anywhere in the Subbasin is significant and unreasonable using the metric of InSAR data.	Motion was passed by Committee and will be incorporated into GSP.	This will be incorporated into GSP development as a strategic comment. See memo for further discussion.
67					Meeting	9/4/2020	Sarah Hardgrave	Re: Groundwater Storage SMC: I would assume that sustainable yield for the Corral Area would include adequate groundwater flow to the Laguna Seca area.	Abby Ostovar: Yes, through SGMA, you cannot impair your neighbor from reaching sustainability.	Meeting comment - noted.
68					Meeting	9/4/2020		Groundwater Storage SMC: Motion to accept Option 1: Pumping in excess of the sustainable yield leads to significant and unreasonable impacts.	Motion was passed by Committee and will be incorporated into GSP.	This will be incorporated into GSP development as a strategic comment. See memo for further discussion.
69					Meeting	9/4/2020		Seawater Intrusion SMC: Motion to accept Option 2. Existing SWI is significant and unreasonable, and SVBGSA chooses to improve SWI. Goal is to push back seawater intrusion.	Motion was passed by Committee and will be incorporated into GSP.	This will be incorporated into GSP development as a strategic comment. See memo for further discussion.
70					Meeting	9/4/2020	Eric Tynan	I appreciate what you're doing. What's going on in Castroville is it's within 2000 feet of our wells, and we're losing well 3. We've been taking measures, so unless we start pushing it back now, we're in a bad spot. I know it's not close to you, but I appreciate what you're doing.	comment received	Meeting comment - noted.
71					Meeting	9/4/2020	Bob Jaques	Your comment about arsenic being naturally occuring, I have friends on a CWS with arsenic levels worsening over time. They have to put in a remediation system	DW: These are the thresholds we're setting. When we talk about undesirable results, degraded water quality as a result of GSA actions is undesirable. In the case of the arsenic that has already been degrading over time, that wasn't caused by a direct action of the GSA, we would not be responsible for that. Abby Ostovar: Even with Option 1, it doesn't prevent you from taking actions that have the additional benefit of improved quality.	Meeting comment - noted.
72					Meeting	9/4/2020	Janet Brennan	My question is related to Option 3. It would appear that it would not be interferring with other agencies?	Abby Ostovar: . We can come back on who is responsible and for what. My understanding is that this hasn't really played out with SGMA yet. It's still unclear. DW: You're right, it's still not very clear. Many other places in the state are taking the "do no harm" approach. You want to work with partners, but not overstep their bounds with regard to partners.	Meeting comment - noted.

73					Meeting	9/4/2020	Justine Massey	We think about water quality from the perspective from individual, domestic wells. They are the least protected and regulated, but are very important to those who rely on them. I agree with comments on how GSAs engage with water quality is not very clear. However, water quality is one of the six undesirable results. We would like to encourage taking care to explore what the situation is for the domestic wells. That would mean not just using deep supply wells, but measuring what the quality is in shallow wells. We support Option 3 here, we think there is a role for GSAs to address water quality. Even if you go with Option 1, we have more sugestions such as DW mitigation program. To reiterate, we think there are many opportunities for partnerships and multi-benefit projects to mitigate the impacts.	Sarah Hardgrave: Thank you for your comments.	Meeting comment - noted.
74					Meeting	9/4/2020	Bob Jaques	On discussion to move on Option 1. I would vote no. I move for Option 3. My friends on a small water system would want to see someone try to do something. You can start with that, and revise it if you see it's not working.	comment received	Meeting comment - noted.
75					Meeting	9/4/2020	Sarah Hardgrave	That raises the question as to whether we can have split criteria for different parts of the subbasin. Arsenic issues may be more of a concern in the Corral area. Can we consider different criteria for different areas, with part of Option 3 as well?	Abby Ostovar: There is still the conversation about management areas and the whole subbasin. We haven't reached out to DWR. There is a question about different options for different aquifers as well. This may be an area to get your input now, not make a decision, but bring back more information.	Meeting comment - noted.
76					Meeting	9/4/2020	Beverly Bean	Regarding arsenic: Different areas have different issues. I don't believe quality is the job of the GSA, it's the job of other agencies. I believe our job is to make the amount of pumping sustainable. If you get the pumping under control, many quality issues resolve themselves.	Comment received	Meeting comment - noted.
77					Meeting	9/4/2020	Janet Brennan	Actions as wtihin other areas, like pumping, will indirectly benefit quality. I still support Option 1.	Comment received	Meeting comment - noted.
78					Meeting	9/4/2020	Bob Jaques	My experience with regulatory agencies is, they will notify you of the problem but they will not take over and solve it for you.	Comment received	Meeting comment - noted.
79					Meeting	9/4/2020	Sarah Hardgrave	One final comment, whether overpumping is exacerbating quality issues needs to continue to be discussed.	Abby Ostovar: Yes, this gives us direction on how to begin writing the GSP, and how to engage with MCWD. We will certainly continue to have these discussions. Donna Meyer: We have initiated conversations with Monterey County Health and we see them as a valuable partner in this. We are learning more about how we can develop the responsibilities and relationship. We're also reaching out to regional board and other agencies to learn more about jurisdictional responsibilities.	Meeting comment - noted.
80					Meeting	9/4/2020		Water Quality SMC: Motion to accept Option 1: Degraded groundwater quality resulting from direct GSA actions is significant and unreasonable as measured by the number of supply wells.	Motion was passed by Committee and will be incorporated into GSP.	This will be incorporated into GSP development as a strategic comment. See memo for further discussion.
81					Meeting	9/4/2020	Janet Brennan	Re: Groundwater Levels SMC: The relationship of this threshold with SWI, comments were made for the 180/400 that setting it at the 2015 level was not consistent with the requirement to address SWI. Maybe it's not as important in this subbasin. Can we have a discussion about that here?	DW: Janet is correct. And here, we are setting SMCs mainly for the Corral area. In the 180/400 we said we will set SMCs for SWI and we would meet them. What we didn't do is incorporate all our SMCs into GW levels. We said we have 6 different things to meet at the same time. What happens is that one of the SMCs will become the dominant driver of how we manage the GW system. They don't have to absolutely integrate. For example if we say we want to stop SWI by injecting water. Our GW levels will rise above the Min Thresh and it meets the requirements. If we say we want to stop SWI by pumping SWI out, our GW levels will drop and we will have to make some adjustments. At this point, we probably don't want to integrate the objectives just yet because we don't know what our projects will be to meet the SMCs.	Meeting comment - noted.

82					Meeting	9/4/2020	Sarah Hardgrave	I did have some thoughts about data needs for the Corral area and GW levels, and what makes the subbasin unique in terms of the proportional share of pumping for omestic purposes versus ag purposes. Looking at what the 180/400 selected, their water demands and purpose are different than in this area. I think our committee primarily selecting an emphasis on shallow domestic wells is reflective of the primary users in this area. I would like more information on the amount of domestic wells and regulated systems compared to the amount of pumping for ag purposes. I see some reason for having different criteria on the GW levels.	Abby Ostovar: Again, this is an iterative process. Other subbasins also came against this where they need more information. We can get initial direction and still come back with more information.	Meeting comment - noted.
83					Meeting	9/4/2020	Janet Brennan	Groundwater Level SMC: Motion to accept Option 4: Impacting shallow, domestic wells is signficant and unreasonable.	Motion was passed by Committee and will be incorporated into GSP.	This will be incorporated into GSP development as a strategic comment. See memo for further discussion.
84					Meeting	9/4/2020	Beverly Bean	Depletion of Interconnected Surface Water SMC: Motion to accept Option 3: The current rate of surface water depletion is not unreasonable (although it may be significant).	Motion was passed by Committee and will be incorporated into GSP.	This will be incorporated into GSP development as a strategic comment. See memo for further discussion.
85					Meeting	9/4/2020	Sarah Hardgrave	Re: Projects and Management Actions: Pumping reductions question: If domestic wells are de minimus users under SGMA, what ability do we have to do pumping restrictions or a water charges framework?	DW: We will include an analysis of that in our data packet. One question we've talked about internally, we don't have reg authority to meter wells, can there be a voluntary system? We'll look into those options as well.	Meeting comment - noted.
86					Meeting	9/4/2020	Janet Brennan	Seems to me the first priority is not to make the problem worse. So, that means no new wells in the area, that's where we begin.	DW: You did point out earlier about Zone B8 overlay. But if it's the suggestion of this committee, we can propose it is expanded and go to the county as the GSA.	Meeting comment - noted.
87					Meeting	9/4/2020	Sarah Hardgrave	I think it would be helpful if you brought back the recommendations of the GeoSyntec report.	Comment received	Meeting comment - noted.
88					Meeting	9/4/2020	Beverly Bean	I agree. We spent $300,000 on that report and we have those recommendations. We may not have the power to implement those, the county does. We don't need to reinvent the wheel, and I think we have enough to go on. If the Country Club is not recycling their water, we can have the county require that they do. Generally speaking, upper Corral area has better supply and quality than lower Corral area well. Is there a way to purchase, pump and store in those areas?	Comment received	Meeting comment - noted.
89					Meeting	9/4/2020	Margaret Anne Copernall	With respect to the SWI, there has been new information on sea level rise being higher than initially thought and the impacts on GW will be severe.	DW: I am familiar with that recent study. We are planning on developing GW models to address these issues specifically. However, we will be making decisions before the results of those models are available. But we will address it.	Meeting comment - noted.
90					Meeting	9/4/2020	Janet Brennan	Are most of the residents on septic systems or sewer? Requiring community sewage collection systems and recycling water could be an approach if there are enough residences on septic. I raise this as a brainstorm possibility.	Comment received	Meeting comment - noted.
91					Meeting	9/4/2020	Sarah Hardgrave	I want to add on. In the Toro Park subdivisions, they are on a wastewater system. It's not exactly a benefit directly to our subbasin. I recall in the Ferini Ranch there was a discussion to connect to Monterey OneWater to get more flow. For the Country Club, I don't think they have a recycled water source for irrigation, but it may be a good idea for an in lieu recharge situation.	Comment received	Meeting comment - noted.
92					Meeting	9/4/2020	Bob Jaques	A couple things, I know Toro Village is sewered to the Toro area treatment plant near the Highway 68 bridge. I think that system was expanded and extended to pick up a little more, not all the way to the Corral area. Looking at the GeoSyntec recommendations, one was more monitoring wells. This would help M&A to calibrate the model so you're not making too many assumptions. Under the GSP, one was to install more monitoring wells. Even though you can't require de minimis wells to report/monitor, but you can ask them and maybe the GSA could get funding for meters. In Seaside we were able to require some wells to provide pumping data.	DW: Yes, for de minimis users we cannot require metering. One question that has come up in other basins is, can we require users to verify they are de minimis users, so they can account for their water use? This is a possible option, but we need a legal opinion if it falls under SGMA abilities or not.	Meeting comment - noted.

93					Meeting	9/4/2020	Sarah Hardgrave	Any sort of recharge project could be expensive. If in the future, the alternative project to desalinate brackish water pumped from the SWI extraction barrier wells was to come to fruition, if aquifer recharge could happen on the southern end of SWI line, if you were trying to mound treated water in the 180/400, if that would have the benefit of mitigating further SWI? And speaking of water gradients, on the other side we may have water leaving this subbasin to the 180/400 aquifer. Would there be benefit to freshwater recharge at those boundary areas?	Comment received	Meeting comment - noted.
94					Meeting	9/4/2020	Janet Brennan	It seems that addressing some of the problems in the Laguna Seca area would also benefit the Corral area. I don't know what kind of projects those would be, but the inter-relationship should be something to consider.	DW: Would you like us to look at what the shortest pipeline runs might be? From CalWater? Or Monterey OneWater? What is the smallest pipe run possible, and how to get water in the pipe?	Meeting comment - noted.
95					Meeting	9/4/2020	Sarah Hardgrave	I think it depends on what projects MCWD would be developing. I think the shortest route is along Reservation Road. Looking at some sort of recharge/injection in the Laguna Seca area, then along a different route. In addition to providing freshwater and recharge, thinking about if it would also have the benefit of halting SWI.	Comment received	Meeting comment - noted.
96					Meeting	9/4/2020	Janet Brennan	Do we have any idea of water consumption at the residential level, such that recommending conservation measures would be a worthwhile approach?	DW: We don't have specific data. The value used in the 180/400 plan was 0.39 AFY per living unit to be used across the basin. It does not include landscaping use, or differentiate large living units and landscaping.	Meeting comment - noted.
97					Meeting	9/4/2020	Janet Brennan	We could extrapolate use from Carmel Valley or Pebble Beach. Those data are available.	Comment received	Meeting comment - noted.
98					Meeting	9/4/2020	Beverly Bean	I think this data could easily be collected. There are several small systems that keep these record, we just need to do the asking.	Comment received	Meeting comment - noted.
99					Meeting	9/4/2020	Sarah Hardgrave	I would like to see a quantification of the water systems (all sizes) and residential connections.	Comment received	Meeting comment - noted.
100					Meeting	11/6/2020	Bob Jaques	Re: Action Minutes for Subbasin Committee Meeting: I find the action minutes for the meetings not to be satisfactory in the sense that there is so little information provided about what the discussions were at the meeting.	Emily and staff: Action minutes are a particular type of minutes which primarily record meeting motions and votes. Comments from Committee members are recorded in the Comment table and the meetings are also recorded. Chair Hardgrave: We have comments captured in the comment table and we have the technical memorandum that provides additional information about motions. My feeling is that we have the comments captured and the information available to support the minutes if needed.	Meeting comment - noted.
101					Meeting	11/6/2020	Sarah Hardgrave	Re: Draft Chapters: I have a question about the two management areas, and coordination with the two GSAs. First question is around the federal lands, and the importance of GSA coverage, combined with statement that SGMA doesn't apply to federal lands. Could you say more about this issue?	Emily Gardner: It's a grey area we don't yet have clarity on. SGMA doesn't apply to fed lands. However, when a GSP is analyzed, they look at if the whole subbasin is covered. We're trying to find the best approach to this grey area. DW: We have received different feedback from different members at DWR. What is more accurate is, we can't tell people on federal lands what they can and cannot do with their water. We do need to cover all the land, including federal land, with the GSP. We just can't tell them what to do. The safest approach is to cover all the land with a GSA. That is what is being done everywhere else.	Meeting comment - noted.
102					Meeting	11/6/2020	Sarah Hardgrave	In the areas in the middle, BLM land, they probably don't have much GW extraction. I'm interested in the federal lands in the north. Like Presidio Monterey. Will those lands be transferred to local agencies?	Patrick Breen: My understanding is that everything has been transferred that will be transferred, and those areas that you are asking about will not be tranferred and will remain federal.	Meeting comment - noted.
103					Meeting	11/6/2020	Sarah Hardgrave	Are those federal areas served by Marina Coast?	Patrick Breen: Yes, under a contract with the Army.The water use will be captured within MCWD's numbers.	Meeting comment - noted.
104					Meeting	11/6/2020	Sarah Hardgrave	It might be worth considering inviting the presidio as a stakeholder.	Comment received	Meeting comment - noted.
105					Meeting	11/6/2020	Sarah Hardgrave	I have a question about the water charges framework for the Corral de Tierra area, if that will apply to the 300 domestic wells you've identified. It may be a future agenda item.	DW: It's something we've talked about internally, and what are our legal options to do that. That's a great future discussion we will have. Abby Ostovar: You'll see in the project and management actions, it is part of pumping controls, and will be a conversation after the allocations workshop. It's very much on our mind, but not something we've worked on and are prepared to talk about today.	Meeting comment - noted.

106					Meeting	11/6/2020	Sarah Hardgrave	There was a difference in the discussion about the deep aquifer. The staff report left out a few statements about pumping from the deep aquifer. I assume this discussion would be included in another spot in the document.	Abby Ostovar: It's something we'll work with MCWD on. It's a difference of where we talk about it. Some chapters include it in the principal aquifer discussion, but we might have moved it to the water budget chapter.	Meeting comment - noted.
107					Meeting	11/6/2020	Sarah Hardgrave	Comment about the piper diagrams that were included in one version and not in another. For the lay person who may not understand piper diagrams, perhaps include them in an appendix. That way the information is available for the technical experts, but it's not in the draft and weighing down the draft chapter for the lay person. If they are included, more explanation of what they are depicting. This comment goes for the cross section diagrams as well.	Comment received	Meeting comment - noted.
108					Meeting	11/6/2020	Beverly Bean	Re: ISW Input: We have other people who have extensive knowledge, Mike Weaver has extensive knowledge.	Abby Ostovar: Local knowledge would be great. Sarah Hardgrave: I agree	Meeting comment - noted.
109					Meeting	11/6/2020	Sarah Hardgrave	You may want to consider talking with representatives from CalAm. They have some facilities near Toro Creek, but I don't know the depth of their wells in those locations.	Abby Ostovar: I think CalAm's wells are much deeper.	Meeting comment - noted.
110					Meeting	11/6/2020	Beverly Bean	Re: Domestic Wells: As a former active person in our local domestic water system, the Monterey County Health Dept. closely monitors us. They have considerable information about the small water systems. The reports we have to complete every year were very complete. Have you considered them as a source?	Abby Ostovar: We have reached out to them, we have not heard back. Emily Gardner: We took this approach because getting this information from the Health Dept. was a complex process. They have a lot of the information, but only some files have all the information we need like well logs. It's a variable data source, much of it is in PDF form, and we have to open each file and read it individually. We've spoken with the Health Dept, and we've taken this approach first before we go down that route.. We can do that, if that's the direction you prefer. Abby Ostovar: We have a number of well logs and that's how we've located which aquifer these wells are in.	Meeting comment - noted.
111					Meeting	11/6/2020	Tamara Voss	We've been working together to get you data. We have a bit of a well log library. If you had APNs, we could make another go at it. Either APN or quarter section. Maybe there's something we can batch give you. I can't guarantee if it could easily be matched to the map. Isn't there someone on the SWIG? Have you reached out to Roger?	Emily Gardner: Roger and Sheryl Sandoval have both reached out back to us, they're willing collaborate. We have to be focused on our ask, and we have to be prepared to go through the documents and figure out how to match them to the dots on our map.	Meeting comment - noted.
112					Meeting	11/6/2020	Beverly Bean	I just want to reiterate the health department does inspect each new well. You'll have current information. These older wells, pre-1995, many are not functional. The health department does inspect when each new well comes online. They do have this information, and it's current. I know it's a lot of work, but it's current.	Abby Ostovar: They continue to inspect the wells? Emily Gardner: You mean taking water quality samples? (Bev: Yes) Abby Ostovar: Do they take water level information? (Emily: No) (Bev: They know how deep they are, and the water level from when it was drilled.)	Meeting comment - noted.
113					Meeting	11/6/2020	Janet Brennan	It looks like there's no problem in Corral de Terra based on your data? Am I reading this correctly? Also, you use many acronyms in your slide. It would be helpful for you to be more descriptive in your presentations.	Abby Ostovar: This is the best we've been able to do with the data we've got. Have you heard of a lot of wells going dry that aren't reflective of what is here?	Meeting comment - noted.
114					Meeting	11/6/2020	Sarah Hardgrave	You're asking, what year would be a good year to set the baseline to measure GW elevations for SMC?	Abby Ostovar: Yes, we're looking at what year were the impacts on domestic wells minimal? DW: Of the wells we know about, there are 50 on this chart. In 2015 and 2017, we think these wells were operable. We would have to have much lower water levels to have impacts in those wells. Is 2015 or 2017 a safe place to set our water levels? We're looking for feedback from this group that 2015 or 2017 are safe enough? Or do you think there were more wells we don't have data to really say?	Meeting comment - noted.
115					Meeting	11/6/2020	Sarah Hardgrave	I'm not sure if Cal Water Service has any comments since they have such a large base of customers, and they have the most familiarty with their well operations during these years. I don't feel able to answer the question about how many wells were impacted. My impression from your chart was that the	Abby Ostovar: I think 2017 is often considered an average year in the valley? DW: It was a little wet, and 2015 being extremely dry.	Meeting comment - noted.
116					Meeting	11/6/2020	Janet Brennan	The Corral de Tierra is in a B8 Zone which limits pumping. These data seem to contradict the B8 designation. Am I reading this incorrectly?	Beverly Bean: The B8 only applies to certain parts of Corral de Tierra and it doesn't restrict pumping. I don't think you legally can restrict pumping. It simply prevents subdivision of legal lots because that is indirectly a way to reduce pumping. Sarah: Yes, B8 zoning is a land use zoning, not necessarily an effort to limit pumping with existing users. Beverly: Specifically the B8 area, is where the GeoSyntec found the most impact from wells.	Meeting comment - noted.

117					Meeting	11/6/2020	Beverly Bean	These well levels relate directly to the drought years. I agree with Sarah. The driest years are the ones you should be measuring from. Also, when I'm talking about wells, I'm talking about small domestic wells and small mutual water systems, when these drought years come and their well goes dry, they just drill another deeper well.	Abby Ostovar: This doesn't capture if one well went dry, and they drilled another. We'd have both records. These are the domestic wells.	Meeting comment - noted.
118					Meeting	11/6/2020	Sarah Hardgrave	This is a sustainability criteria that is based on the domestic wells. This captures a portion of the domestic wells constructed since 1995, the more	Abby Ostovar: We can update this in the future. Abby Ostovar: So I understand the MT recommendation is 2015.	Meeting comment - noted.
119					Meeting	11/6/2020	Bob Jaques	Re: Wallace Group Memo. It says the purpose was to estimate water extractions, and to estimate available recyled water. It seems like they didn't really complete the task. At the end they talk about information gaps that prevented them from getting handles on those numbers. I have a few ideas. Looking at page 6 and 7, they talk about Cal Utility Service. It seems the Regional Water Board would have waste discharge reports because they all have to be permitted. I've been able to get this information. I would encourage looking at that. Second, on page 7, they have a table of estimated WW flows, the figure for residential indoor domestic use looks awfully high to me. The water reuse on that same page, Las Palmas, there may be additional waste water that could be used from that plant elsewhere in Corral de Tierra.	Abby Ostovar: You're right, the WW is high and the Projects document has the updated number.	Meeting comment - noted.
120					Meeting	11/6/2020	Sarah Hardgrave	Re: Wallace Group Memo: Las Palmas is within the County service area and they are in the process of updating some of the reports. I think the county will have more information available for the WW capacity for that system in the next few months because of a development proposed in that area and they are reporting to the Regional Board. I can ask county staff to provide that.	Comment received	Meeting comment - noted.
121					Meeting	11/6/2020	Janet Brennan	Re: Projects and Management Actions: In terms of use of GW from the Upper Corral Canyon, who would do that? I don't understand who would be doing that? Are we talking about the public water agencies?	Abby Ostovar: The GSA could take actions, we have to figure out who would finance them. I don't know, since it's outside the subbasin boundaries. We could always partner with somebody. Les: The GSA has independent authority to do a variety of things. There are other agencies which have authority. We could form more JPAs, and there are many ways to partner with other entities that have authority.	Meeting comment - noted.
122					Meeting	11/6/2020	Beverly Bean	Re: Projects and Management Actions: Encouraging domestic conservation. In my experience, the people who have small systems or their own wells are not amenable to conservation. During the drought, we observed in our group that we were the only ones that reduced our water use. No one else did. Conservation has been successful on the peninsula because they can reduce your water pressure way down. How can we enforce conservation?	Les: In my opinion, the GSA can regulate extractions of de minimis users, but we can't make them report their extractions. MCWRA can regulate extractions, they have never done so, but they have that authority. Monterey County can also regulate extraction under certain circumstances.	Meeting comment - noted.
123					Meeting	11/6/2020	Les Girard	The GeoSyntec report was commissioned by Monterey County Resource Management Agency, not MCWRA. And the B8 Zone was adopted from that which is a limitation on development.	Beverly Bean: The B8 overlay was in effect since 1992, the GeoSyntec report supported it and allowed it to continue.	Meeting comment - noted.
124					Meeting	11/6/2020	James Sang	I'm really interested in water recharge. I like the use of recycled water instead of GW. It would be dependent on what the residents feel about it. I think it's a good source of water. The use of GW from upper areas, requires a lot of money to build pumps and piping and tanks. Re domestic conservation, I agree with Beverly that people are not willing to do it. I don't like pumping limitations. I like the idea of recharge, but I would like to know exactly where the water is coming from that people are using. If it's coming from wells, we should do collection and recharge around that well.	Comment received	Meeting comment - noted.

125					Meeting	11/6/2020	Sarah Hardgrave	This exercise and this presentation really reinforced the challenge of this particular area, in terms of options for recharge in particular. I was concerned about seeing more details on the limitations and the physical geology of the area, being limiting factors. The decentralized recharge areas and basins, I think there are opportunities for that, but it will be a drop in the bucket. It wouldn't provide as much as benefit, would not have a significant effect in terms of GW levels. This is a rural residential area, so there isn't infrastructure in place for bioswales and that intentional, "Slow it, Sink it, Spread it concept". It also didn't seem like it would result in a lot of recharge to the aquifers. The recharge from runoff is pretty minimal. I think it would be worth it to look at extensive educational program with homeowners. This area is not part of the county's municipal stormwater program. There is extensive materials and information out there with the county RMA, for collaborative efforts in this area, but I'm not fully convinced it would have big bang for the buck.	Comment received	Meeting comment - noted.
126					Meeting	11/6/2020	Beverly Bean	I support what you're saying about recharge. Most of the small users' wells are already at 300-400 feet. Recharge would not be very successful at that depth. The golf course just drilled a new well at 800 feet deep. My strong feeling is enforcing pumping limitations is the only way forward. Legally, we can do it, how do you implement it? I would like to see more details on the last item (pumping limits).	Comment Received	Meeting comment - noted.
127					Meeting	11/6/2020	Sarah Hardgrave	I think at this point in time, I would recommend not taking anything off the table entirely. None of these is a silver bullet. There are a lot of challenges. I would like to see how we can incentivize conservation. Maybe now with the GSA, there is more authority to enforce it and maybe we can approach it differently.	Comment Received	Meeting comment - noted.
128					Email	11/6/2020	Bob Jaques	Re: Project Ideas: Programs and Actions should include: "Coordinate with Seaside Basin Watermaster to mitigate lowering of groundwater levels in the Laguna Seca Subarea" To meet SMC measurable objectives, should include addressing overdraft in the Seaside Basin Laguna Seca Subarea.	Comment received.	
130					Meeting	1/7/2021	Sarah Hardgrave	Are you going to develop a long-term sustainable yield for the two management areas or for the subbasin as a whole?	Abby Ostovar: We have to calculate overdraft as a subbasin, but still need to discuss with MCWD. If only for informational puporses, we will do this for each management area, but we haven't discussed how this all works yet. Have to check what's in the regs, what we can do legally and well as what we want to do. For this conversation, focused on the corral de tierra area. I'm not asking you to make decisions today, this is just to inform you and get you thinking. This is an intermediary step.	Meeting comment - noted.
131					Meeting	1/7/2021	Sarah Hardgrave	It seems like allocations are more easily applied in areas where there are more ag/irrigation users, and not as easily in areas that are predominantly rural and residential areas. Are the Cal-Water and Cal-Am in the Corral area service systems considered municipal systems?	Abby Ostovar: I'm pretty sure, I'll check on it. They would be different than mutual water systems, not overliers.	Meeting comment - noted.
132					Meeting	1/7/2021	Janet Brennan	I think addressing this issue depends on if a pumping allocation system can even be implemented in this area. It seems that a large portion of the water users are beyond the regulatory process.	Abby Ostovar: We can regulate de minimis users. You can regulate them, you just can't meter them. Tricky because you don't know what they are actually pumping.	Meeting comment - noted.
133					Meeting	1/7/2021	Janet Brennan	How do you know they're meeting their allocation?	Abby Ostovar: If there was a connection basis, you could have a set amount per connection. Say you have 1000 AFY and you have 500 connections, and 100 are de minimis users. You could count them as connections and that would be their slice of the pie. It's an approximation.	Meeting comment - noted.
134					Meeting	1/7/2021	Janet Brennan	I guess the question in terms of percentage of users, what percentage are de minimis, what percentage are overliers?	Abby Ostovar: I don't have the percentages here. Do you want to treat municipal systems different than mutual water systems? You can, you don't have to.	Meeting comment - noted.
135					Meeting	1/7/2021	Janet Brennan	Why would you differentiate?	Abby Ostovar: The categories the state uses are overliers and non-overliers. But mutual and municipal are both for domestic use.	Meeting comment - noted.

136					Meeting	1/7/2021	Sarah Hardgrave	It seems that the municipal systems, the Cal-Water service and Cal-Am are serving neighborhoods or developments that are more akin to a medium density residential area, whereas the mutual water systems may serve larger lot property owners. I'm not sure you could treat them equally. Those larger lot owners may have horses, or a small vineyard on their property that may account for more water use. I think that's something we need to consider. In the B8 Zone, the recently adopted county regs for accessory dwelling units do not allow ADUs within the B8 Zone area. So that is not a consideration for future demand, within that B8 portion of the management area. Not all of the management area is in the B8 Zone. In the B8 zone, there's no further subdivision according to the zoning. I don't know how much subdivision potential there is outside of the Zone, but I think it's probably limited. I recommend looking at the county land use plan for the Toro area for an indication of potential growth to use for the calculation of a set aside. I don't think it will be a substantial amount.	Comment received.	Meeting comment - noted.
137					Meeting	1/7/2021	Beverly Bean	Question about the difference between municipal as those being served by Cal-Am or Toro water, compared to the mutual systems formed from residential users. Water source. Mutual water systems pump from wells close to their properties. Where are the wells used by Toro and Cal-Am?	Abby Ostovar: We know where some of the wells are. As far as overlying rights, the mutual water systems' wells are right there, and they can't move that water. We can look at how far away the wells are of the municipal water systems. My guess is that it isn't that far, so it won't make that much of a difference.	Meeting comment - noted.
138					Meeting	1/7/2021	Beverly Bean	You believe they're all within the Corral de Tierra subbasin?	Abby Ostovar: I believe so. We will look at those along the edge.	Meeting comment - noted.
139					Meeting	1/7/2021	Jon Lear	I just want to say as far as Cal-Am pumping in this area and pumping in the Laguna Seca area, there is going to be a change in the Laguna Seca area because the most recent general rate case has CalAm building an intertie to their main system, so there will be an overall reduction in the Laguna Seca area. The corral de tierra area, still plan to have that area pumped. No plan to tie-in to larger system.	Comment received.	Meeting comment - noted.
140					Meeting	1/7/2021	James Sang	I wanted to know exactly how it is being determined you're in overdraft. Are you going to different wells and just judging by how far you reach the water? And in the future, if you're able to get enough progress to bring the water level up, how does that affect the pumping allocation? Last November, we discussed some projects but they didn't seem to really be able to increase the GW supply. I think there are other projects that can be recommended. In Langley, they recommended rooftop water harvesting. I think that's good for anyone that's on a well to reduce their pumping. There are some people who have 5,000 gal tanks. On a 15inch rainfall year on a 1,000 sq ft roof, you can get 9,000 gal. I think it's possible to harvest rainwater and get it into the GW but using the slopes. You could do it by trenching the surface of the hills to collect more of the rainwater, and prevent it from being evaporated and allow it to sink into the soil in the hill and allow it to sink into the ground. How do you determine overdraft?	Abby Ostovar: We use a groundwater model. We're actively working on it. They're very complex models, you have to take in the stratigraphy and climate. We're working on it. We're hoping to have a budget for you soon. For recharge projects, if you put more in the ground, you can take more out. However, there are not great recharge options in this area. There isn't a steady supply of surface water in the area. We're working on scoping a larger recharge project. We've looked at scoping decentralized rainwater harvesting. It will be very challenging to meet the sustainable yield just with those types of projects. There are over 300,000 gal in an AF. The amount you collect on an individual house may help that house, but getting enough homeowners to participate is a very challenging task. We want to pursue it, but we have to look at the numbers to see if we can meet sustainable yield. For a larger recharge project, there is also the question about how to pay for it. Pumping allocations, even if not used for reductions in pumping, could be a way to allocate the financing structure to pay for these kinds of projects.	Meeting comment - noted.
141					Meeting	1/7/2021	Sarah Hardgrave	Given land use in the area, and the residential areas, has there been much fluctuation in pumping over time, or has it been fairly consistent?	Abby Ostovar: One of my staff has looked more at this, but it only goes back to 2013.	Meeting comment - noted.
142					Meeting	1/7/2021	Beverly Bean	I would say the majority of development has happened in the last 50 years or less. I've been here for the last 40 years, and growth was unchecked from the 70s and 80s on, and with the flimsiest ideas of where the water would come from. Historically speaking, I don't know what time frame you're talking about. The growth since the 60's and 70's has been steady. The number of people living here has steadily increased. The groundwater levels are steadily decreasing.	Abby Ostovar: We don't have data for water systems prior to 2013. We could take an average between 2013 and 2018 but that includes a drought. For individual households, we don't have that data, but we could look at the number of households.	Meeting comment - noted.
143					Meeting	1/7/2021	Janet Brennan	If you use historical pumping as the basis of an allocation system, historical pumping has created the problem. So is it historical pumping minus a percentage?	Abby Ostovar: The historical pumping would basically say, 2013-2018, average water use sets up the pie. Your sustainable yield determines the size of the pie. Could be smaller. It just sets the basis for the overall allocation.	Meeting comment - noted.
144					Meeting	1/7/2021	Janet Brennan	Historical pumping seems to be a fair way to allocate water use. I mean, it reflects actual use for all systems, except for de minimis.	Abby Ostovar: The argument against historical is that it rewards those who have caused the problem.	Meeting comment - noted.

145					Meeting	1/7/2021	Janet Brennan	If you have an allocation based on historical use, how does it increase water use?	Abby Ostovar: If you have 2 neighbors, and one has been pumping and irrigate all their land, and the other hasn't, how much they've been pumping determines how much they use in the future. The one who has pumped a lot can continue to pump, and the one who has conserved cannot. Emily Gardner: It would have to be changed proportionally. Abby Ostovar: Right, if you've always used less, you will always use less.	Meeting comment - noted.
146					Meeting	1/7/2021	Beverly Bean	In terms of this historical pumping, if you've caused problems in the past, why should you be allowed to continue that? In my mutual system, we have an allocation of basic use of 30,000 gal per quarter per household. If you go over that, you are punished by a severely higher rate. Maybe those kinds of numbers are the way you need to look at this. If you go by household, what's a reasonable number and if you go over that, you have exceeded your allocation.	Abby Ostovar: There are two more options, by household/building structure or connections. Net acreage would be another one. Sarah mentioned that some people have other uses, like horses. How do you deal with that in your mutual water company?	Meeting comment - noted.
147					Meeting	1/7/2021	Beverly Bean	Having horses is a choice. If you can do it within your allocation, you can do it. The problem is with affluent people, I'm not sure the cost is a deterrent. We don't make special circumstances for what people do on their property. If you use more you pay more. I'm not sure that is a sufficient deterrent.	Comment received.	Meeting comment - noted.
148					Meeting	1/7/2021	Janet Brennan	Could have allocation based on households plus acreage, a hybrid, to account for people who have horses.	Abby Ostovar: It's a fair point that there are other uses than just domestic use.	Meeting comment - noted.
149					Meeting	1/7/2021	Sarah Hardgrave	Some people have swimming pools and other household activities.	Abby Ostovar: The question is "what's fair", does each household get the same? Should allocation be based on acreage and use?	Meeting comment - noted.
150					Meeting	1/7/2021	Sarah Hardgrave	If you fly over this area, there is a quite a bit of variation in size of houses. There's probably some houses over 10,000 ft^2 and other houses that are 2,000 ft^2. That's a challenge in this area to consider. I think that's where a hybrid that considers the lot size might be appropriate.	Abby Ostovar: Would you weigh those equally?	Meeting comment - noted.
151					Meeting	1/7/2021	Sarah Hardgrave	I feel we don't have enough information to weigh in at this point. It would take some better understanding from the land use perspective to propose a hybrid.	Abby Ostovar: If you're in overdraft, this will be one of the ways to meet sustainability. Post GSP there will be more of a process, more stakeholder discussions. Here, this is the foundation. The more input we have now, the better we can come back. When it comes to overliers vs non overliers, should those have a similar metric and allocation or should we have something distinct for those?	Meeting comment - noted.
152					Meeting	1/7/2021	Janet Brennan	I'm not sure why we would want to differentiate between municipal systems and overliers. We should use the same approach for both.	Comment received.	Meeting comment - noted.
153					Meeting	1/7/2021	Sarah Hardgrave	I would agree with you, Janet, because the areas served by Municipal systems, Toro Park, Las Palmas, those are more suburban density neighborhoods, so if you're using some sort of lot size or acreage, that would be reflected. Or those areas would be more likely to have the 0.4 AF househole usage versus someone higher up in corral who has a 10-acre property.	Comment received.	Meeting comment - noted.
154					Meeting	1/7/2021	James Sang	On this issue, what this program is dealing with is if you're getting in overdraft or not. If Cal-Am or Cal-Water has their water source far away, I don't think they should be included unless their source of water is connected to this aquifer.	Sarah Hardgrave: These are satellite systems that are operated by these two utilities that draw their supply in this system. They are neighborhood scale systems that have the source of supply in area.	Meeting comment - noted.
155					Meeting	1/7/2021	Beverly Bean	These dormant overliers, if these are what we call legal lots of record, aren't they entitled to water? We're just counting them in so we can make a water budget?	Abby Ostovar: Theoretically, you can just say they don't get any. She cautioned against that. Either you account for them when they start using, or you set aside part of the pie.	Meeting comment - noted.
156					Meeting	1/7/2021	Beverly Bean	Are these legal lots of record? Simple enough to find out who they are and how many there are.	Comment received.	Meeting comment - noted.
157					Meeting	1/7/2021	Sarah Hardgrave	I agree, from the county's land use perspective, there would be a significant issue if legal lot of record were not accounted for in the budget.	Comment received.	Meeting comment - noted.
158					Meeting	1/7/2021	Sarah Hardgrave	Re: Municipal growth: I think that would be pretty easy to quantify because the potential for that kind of growth is limited for this area. Different question for Marina area and former ft ord.	Comment received.	Meeting comment - noted.

159					Meeting	1/7/2021	Janet Brennan	All I can say is best of luck getting legal lots of record from the county. The county always punts and says it's too detailed. It's crazy. It's not going to be easy Sarah, to find these legal lots in the Toro area. Nobody knows how many legal lots of record there are for the county. Maybe looking at the land use plan and getting a sense for how much development could occur may be the best way.	Comment received.	Meeting comment - noted.
160					Meeting	1/7/2021	Sarah Hardgrave	Did the general plan, 2010 EIR quantify this in any way?	Janet Brennan: No. For example, in Carmel Valley the number of legal lots of record has ranged from 500 to 250 over time, depends on who you're talking to. I don't think we can ask them to get a feel for vacant parcel that could be developed. That's probably the best question rather than legal lots of record which is a more detailed analysis.	Meeting comment - noted.
161					Meeting	1/7/2021	Sarah Hardgrave	Seems like you could look at assessors code for vacant property. But it's an imperfect number. I don't know how into the weeds the GSP needs to get. I do think it would be important to have some general estimate for making sure the potential is accounted for within a sustainable yield allocation. In terms of substantial municipal growth in this area, there's not a lot of room for it. The one major subdivision that was proposed has gone into a conservation easement.	Comment received.	Meeting comment - noted.
162					Meeting	1/7/2021	Beverly Bean	I would like to say a de minimis user could have a large estate property and use a large amount of water. They have their own wells for the property.	Abby Ostovar: De minimis is defined as those using less than 2 AFY. You have to somehow determine how much they're using.	Meeting comment - noted.
163					Meeting	1/7/2021	Beverly Bean	How do you ask them or determine that?	Abby Ostovar: For a 0.4 AFY, that's 5 households under 2 AFY.	Meeting comment - noted.
164					Meeting	1/7/2021	Beverly Bean	Some have vineyards or pools, I can imagine they're using that much water if they are growing grapes. If you can't meter them, how can you know anything?	Abby Ostovar: You could do an estimate to include them in it. You can still do net acreage. DW: It's a difficult question. Self-certification, and then they have to demonstrate they are de minimis. None of the approaches are perfect. No matter what decision we make, we're going to have to draw a line. And if people have issue, they will have to prove it.	Meeting comment - noted.
165					Meeting	1/7/2021	Sarah Hardgrave	I think it would be helpful if you can bring back alternative proposals that include/exclude [de minimis users] based on your further investigations. If we're using some sort of acreage factor, that should be considered in a hybrid approach.	Comment received.	Meeting comment - noted.
166					Meeting	1/7/2021	James Sang	I think de minimis users should be included, and dormant users should not. If they don't have a well and they're not extracting water from the aquifer. If people are drawing water from the aquifer, they should be charged. If they are not, they should not be charged.	Sarah Hardgrave: There's the question of the allocation amount, and the question of what you do with it. That's a future discussion. Abby Ostovar: Typically dormant users are not charged, even if there's space in the pie for them, if they're not using.	Meeting comment - noted.
167					Meeting	1/7/2021	Janet Brennan	Re: Prioritization of pumping controls: Our response depends on what alternatives we're looking at. If there are projects that will increase supply and are cost effective, our answer will be different than just out of the blue. We need more data.	Abby Ostovar: We're working on that.	Meeting comment - noted.
168					Meeting	1/7/2021	Sarah Hardgrave	I would concur with Janet. It seems like our supply projects are really limited in opportunity. It's hard to answer that question without understanding what those options might be.	Abby Ostovar: I'm hoping next time, these parts will come together. We'll try to come up with some kind of proposal or some kind of allocation structure based on this conversation.	Meeting comment - noted.
169					Meeting	1/7/2021	Janet Brennan	What I got out of it is that the data from the Stanford study (AEM) and the Marina Coast area, there was no inconsistency with that data and MCWRA data. Did I read that correctly? My understanding is that there is a lot of conflict with this data and County resources.	Abby Ostovar: The AEM data informs how we understand the basin. I don't know how is conflicts with MCWRA data. DW: I think the consensus is that AEM data generally supports the conceptual model. People have noted there are specific areas where there are some discrepancies. Your concern is about discrepancies?	Meeting comment - noted.
170					Meeting	1/7/2021	Tina Wang	Re: Discrepancies between Stanford and county data. Our plan has said that in the lower 180 and 400- aquifer, which is currently SWI intruded, the AEM data is consistent with the MCWRA chloride maps. There is one thing we pointed out in that chapter, is the dune sand aquifer and the upper 180 foot aq is not SWI intruded, it is fresh. That's a slight difference with the data published by the county. It does not distinguish the specific conditions in our subbasin that is seperated into the upper 180 that isn't intruded and the lower 180 that is intruded.	Comment received.	Meeting comment - noted.

171					Meeting	1/7/2021	Tamara Voss	Re: Discrepancies between Stanford and county data. Number 1, the agency the does not collect data in the Dune Sand Aq. We also don't break down the 180-foot aq into an upper and a lower. This report seems to group the lower with the 400, instead of with the upper 180. We'll have to have further discussion. I'd want to further understand what EKI defines as fresh water, before I would say the upper 180 is not intruded near the coast. It would helpful to define the geographic extent where the consultant is defining freshwater.	Comment received.	Meeting comment - noted.
172					Meeting	1/7/2021	Sarah Hardgrave	In follow-up to this, I would like to suggest inviting Tamara to one of your TAC meetings to further explore these questions. Seems there is a need for further technical discussions in order to address Janet's question about the discrepancies.	Comment received.	Meeting comment - noted.
173					Meeting	1/7/2021	Bob Jaques	With regard to the AEM data, if I recall correctly, in conjunction with CalAm's slant well desalination planning and EIR process, I think the county convened a blue ribbon panel of hydrologists to review. I believe they evaluated the AEM data and rendered their opinions. They had some concerns about how valid that data was. One of my comments in regard to chapter 5 would be that there should be some language in the document that reports on what that panel's findings were regarding the AEM data. They had some concerns about that data being used.	DW: We have discussed the AEM data with some members of the blue ribbon panel. We did talk to some members, they didn't have too many concerns. I will look at some of the specifics of what was brought up today.	Meeting comment - noted.
174					Meeting	1/7/2021	Bob Jaques	Some additional comments: there are so many acronyms, there needs to be an acronym page in the front. It would help me follow the discussion. In the Seaside, we have 3 aquifers, Aromas, Paso, Santa Margarita. I would like a figure that shows the relationship between the different aquifers and where different terminology is being used. I think they're all connected, but they seem to have different names based on which basin you are in.	Comment received.	Meeting comment - noted.
175					Meeting	1/7/2021	Sarah Hardgrave	A suggestion, in terms of the figures, in figures 1-10, if you could put the 2017 and 2018 figures together, you could see the comparison across the years more easily instead of flipping between fig 1 and fig 5 (several pages away). There are some statements around the Deep Aquifer levels decreasing over time. I was wondering if those kinds of analyses are being included in the Deep Aquifer working group as well as with the SWIG, and also if this subbasin is being included in those committee discussion. I'm cognizant of the concerns of MCWD of the Deep Aquifer and the other parts of the valley, I want to make sure these concerns are being heard.	Abby Ostovar: We've worked very well with EKI, and been involved with these discussions. We wanted to get something out to this group. It just takes time to get through this coordination. We'll take this input and keep working.	Meeting comment - noted.
176					Meeting	1/7/2021	Patrick Breen	The Deep Aquifer presentation was shared with the SWIG.	Comment received.	Meeting comment - noted.
177					Meeting	1/7/2021	Janet Brennan	Regarding the findings of the Deep Aquifer I thought that was the outstanding information in this report. It's the most alarming, and good information I've seen.	Comment received.	Meeting comment - noted.
178					Meeting	1/7/2021	Sarah Hardgrave	Statements around connection between aquifers, the Deep Aquifer being hydrologically connected to the Santa Margarita in the Seaside Basin and the Paso Robles being connected in another place. Connectivity, and concerns for the Seaside basin. Page 31 talked about FO 10 and FO11 monitoring wells and the Seaside watermaster report address those monitoring wells as well. I want to make sure those statements being reported here are consistent with what is being reported to the Water Master. The Pumping tough north of this area, I would like to know what that means for this subbasin.	Abby Ostovar: The pumping trough is part of what EKI and MCWD presented to the SWIG. DW: Historically, the Deep is considered Lower Paso and below. And Santa Margarita gets pulled in. We're waiting to see just how connected all those really are. We're looking forward to seeing the Deep Aq investigation come out. Abby Ostovar: It may make more sense when CH 4 is released, and the rewrite.	Meeting comment - noted.
179					Meeting	1/7/2021	Sarah Hardgrave	SWI, and the MCWRA lines with large swaths with question marks. How do we reconcile those areas where we don't have monitoring well information at the front of the SWI lines. How, in this subbasin, where additional monitoring wells will be needed. I think I brought that up at the MCWD meeting as well.	Comment received.	Meeting comment - noted.

180					Email	2/23/2021	Beverly Bean	page 24 -section 3.1.5 delete the Ft Ord Reuse Authority(FORA) which was disbanded in 2020 page 46 section 3.5 1st paragraph eliminate the sentence about FOR A	Comment received.	
181					Meeting	3/5/2021	James Sang	For every 1% of temperature rise, water vapor increases by 4%. Carbon rises and the ground has been drying up. You see this in the hills in the Corral area when you're driving. We have to capture that precipitation when it's coming down, and increase the soil moisture. For us to have rain, we have to have enough soil moisture. We have to capture that precipitation in the ground.	Comment received.	Meeting comment - noted.
182					Meeting	3/5/2021	Sarah Hardgrave	For the minimum threshold historically observed between 1995 and 2015, is that an annual average? Did the levels fluctuate over those 20 years?	Tina Wang: How it will be measured exactly, we will use water levels collected from November/December compared to water levels collected in November/December. For each well, we will look at the lowest water level observed in November/December between 1995 and 2015 and use that as the minimum threshold. Abby Ostovar: The distinction for the Corral area is that we have selected only 2015 water levels. In a similar way, they will benchmark the representative year, and that will become the threshold year. And they're taking a short timeframe since MCWD was formed. It will roughly mirror our approach. Essentially a very similar approach. Patrick Breen: And just to clarify, some water levels are different within that period of time. There are differences amongst the wells, where 2015 was not the lowest year.	Meeting comment - noted.
183					Meeting	3/5/2021	Sarah Hardgrave	I think this information is important for the next part of the presentation. But as for decision-making, we still have to review this information.There is a lot of incredibly valuable information in the packet. But I hadn't see the 1,700 AF/yr until now.	Comment received.	Special meeting scheduled to provide direction on SMCs
184					Meeting	3/5/2021	Janet Brennan	I see that decisions about projects and management actions are related to sustainable yield, and that information isn't provided. We can move ahead based on other factors, but we still need to know that to make decisions. Maybe at future meetings, that inter-relationship between sustainable yield and projects can be defined.	Abby Ostovar: Absolutely. I'd still like to go over the projects and management actions so you can provide strategic direction on what you want us to focus on. We're on a tight timeline to put together the GSP.	Meeting comment - noted.
185					Meeting	3/5/2021	Bob Jaques	Re: MCWDGSA Indirect potable reuse project: Would this water come from Monterey One Water?	Vera Nelson: That's correct. Patrick Breen: What this doesn't solve is the whole universe of source water. We know CSIP is looking to expand, there's the possibility of river water. I don't want to say MCWD has a particular volume of water and we're going to inject it. This is a conceptual model that assumes there is water that needs to be treated. We're not making some sort of claim. This is a conceptual project for injection. The source of the water to be treated is to be determined.	Meeting comment - noted.
186					Meeting	3/5/2021	Janet Brennan	This item is not on the agenda. What is on the agenda is projects that will benefit the Corral de Tierra area.	Comment received.	Special meeting scheduled to discuss Marina-Ord Management Area projects.
187					Meeting	3/5/2021	Marieke Desmond	Patrick, what other sources (I know this is introductory), what other sources of water would potentially be used for recycled injection? If there are any other sources that can be used?	Patrick Breen: We have existing flows to the plant currently, municipal sewer, or water in the Blanco drain, or other drains going to SRDF. There may be new sources that come on in the future from the river or otherwise. It will be water that goes through the plant for treatment before we can put it in the ground. There is no new source we're speculating about.	Meeting comment - noted.
188					Meeting	3/5/2021	John Bramers	Going back to the monitoring wells. How many wells are in the networks? I think there was an a, b, c. What wells? Are they domestic? Ag? What are they? Mainly the MCWD side.	Tina Wang: We'll be sharing a map of the wells at the MCWD stakeholder meeting. In each aquifer group, we have 9-13 monitoring wells, so 20% means about 2-3 wells exceeding MT would result in an undesirable result. They are only monitoring wells. As a background, water production in this area is limited to MCWD municipal use. There are no identified domestic or Ag use.	Meeting comment - noted.

189					Meeting	3/5/2021	John Bramers	You mentioned recharged for the Deep Aquifer. Do you have a study on that already?	Vera Nelson: What we've done is a feasibility study. We've done an analysis where we would have to inject with the timeframes required for pathogen reduction. But we have not done any geochemichal analysis with regard to compatibility. We have looked at where we could inject relative to gradients of existing wells, and how viable that would be.	Meeting comment - noted.
190					Meeting	3/5/2021	John Bramers	I have one more question. It's about injection over the winter months. Is that the best time to do it?	Vera Nelson: The greatest availability of water is in the winter months. For a municipality, the timing doesn't matter as much, it's just more available. It allows the farmers more water for use in the summer months.	Meeting comment - noted.
191					Meeting	3/5/2021	Bob Jaques	If you're doing stream diversion for recharge into the Corral area, are you looking at other downstream effects on users that would benefit from that water naturally recharging?	Abby Ostovar: That analysis will be done later during the feasibility study.	Meeting comment - noted.
192					Meeting	3/5/2021	Beverly Bean	This comment is strictly addressing the first potential project, the rubber dam. I find it bizarre coming to these meetings and then going to the Toro LUAC. We're continually seeing new [housing] projects added to the area using existing water systems Cal-Am and Toro Water, but these systems are still pumping from this basin. On one hand we're talking about ridiculously expensive projects, and on the other hand there is no moratorium on continuing to add pumping to the basin? Do we have authority to restrict pumping?	Sarah Hardgrave: We're getting to that in the pumping allocations discussion.	Meeting comment - noted.
193					Meeting	3/5/2021	Janet Brennan	My reaction to the project list is that recharging the basin is more efficient than anything at the homeowner level, they almost don't seem viable. I did look at the pumping per connection on Page 4 of the analysis. I did look at the amount of water per connection. There are parts of the Corral Area Subbasin that have excessively high water demand per connection. Salinas Hills has a per unit connection of 0.73. There are four or five areas that have an excessively high water demand per connection. Based on that, and this may not be accurate, this points to the directions for the need for a demand allocation.	Abby Ostovar: Thank you, Janet. The analysis was done by Wallace Group to help this committee because we don't have great pumping data here. For the water systems we do have data, there are some that use 0.7 and others that use 0.2. For the water systems where we have data, larger than 15 connections, we use those values. For the estimation for *de minimus* pumping we use 0.4 AF per household, which may also be underestimating it. When thinking about pumping allocations, if you think that value is significantly low, then more work may need to be done.	Meeting comment - noted.
194					Meeting	3/5/2021	Bob Jaques	One of the projects listed in one of the earlier reports talked about using recycled water for irrigation. Could you explain why that is not on the list?	Abby Ostovar: I do have a slide that was a backup slide. Wallace Group did look into wastewater. There are two main sewage systems in this area. One uses this water for medians. We have not been able to find out if the golf courses use recycled water. There is potential for greater water recycling. There has not been interest in the past from WW operators to do recycling. We're looking at incentive programs, or looking at SVBGSA to incentivize those actions.	Meeting comment - noted.
195					Meeting	3/5/2021	Sarah Hardgrave	In the Las Palmas subdivisions, served by Cal Utilities service and Cal Am manages wastewater. They do have recycling of water in that area, which is one of the larger water municipal users. There is some recycling that is occurring in this area and in separate conversations with CalAm's current rate case, that recycling system is very expensive to operate.	Comment received.	Meeting comment - noted.
196					Meeting	3/5/2021	Bob Jaques	I was thinking the Corral de Tierra Golf Course as one of the larger water users in the area, would be a potentially good candidate for recycled water. In any event I think it would be important to look far enough into the golf course as a regional water user as one of the potential reuse projects. It may be so cost prohibitive, but I don't think it should not be an option.	Abby Ostovar: It was a comment from the Wallace Group as well, that further waste water recycling had a high cost. However, we can still list it as an option.	Meeting comment - noted.
197					Meeting	3/5/2021	Sarah Hardgrave	Well, you have some other expensive projects in there, I don't see why this [waste water project] couldn't also be included.	Comment received.	Meeting comment - noted.
198					Meeting	3/5/2021	Christopher Bunn	To add to the wastewater discussion, there's an opportunity. Cal Utilies Services treats the water and then disperses it in spray fields, just to disperse it. There's going to be a bridge at Davis Road, it could include a pipe underneath, and would be quite close to the main sewage lift station for the City of Salinas and then it could be injected and moved to Marina.	Comment received.	Meeting comment - noted.

199					Meeting	3/5/2021	Sarah Hardgrave	I want to add to build on what MCWD described and build on regional projects. If there were a desal or brackish water plant project in the Marina area serving MCWD down to East Garrison, extending a pipeline down the bluffs and then to Toro Park and Las Palmas, looking at municipal users, that was 64% of total usage. Looking at current materials, current pumping is 2400 AF and 64% in urban systems, and sustainable yield is 1,700, if we could have an alternative supply to those areas, we could reach sustainability. It's pie in the sky at the moment. In terms of this analysis for this area of the subbasin, it would be good to include a potential cost of a pipeline from East Garrison down reservation road to those utilities. I'm just throwing it out there. I hope you will consider it for future discussion.	Abby Ostovar: We've been looking for new ideas as well.	Meeting comment - noted.
200					Meeting	3/5/2021	Beverly Bean	I just want to comment on your comment about the B8 Zone. That is a very small part of this subbasin. It is only preventing subdivision, and there are constant efforts to overturn it and change it. The rest of the area is open to development. In the LUAC, we constantly see more houses going in. So the B8 Zone is just a small part of this area.	Abby Ostovar: Thank you. If and when allocations are developed, there will be a much more refined analysis.	Meeting comment - noted.
201					Meeting	3/5/2021	Beverly Bean	Re: Pumping allocations. I want to comment that the golf course should be included in every one of these charts. They have new wells at 800 feet. We're not allowed to know how much they're pumping. We should try to estimate how much it is.	Abby Ostovar: I don't have it included here, but Wallace Group has that estimation of their water use. They have overlying rights, so you can consider them in the overlier portion of the chart as well.	Meeting comment - noted.
202					Meeting	3/5/2021	Janet Brennan	Drinking water systems, are they municipal, or are they not identified on the chart? Thank would be helpful to include on the chart.	Abby Ostovar: DW systems are municipal systems and mutual water systems. We also included an allocations memo, where it is explained more. But thank you for your suggestion to include in our chart.	Meeting comment - noted.
203					Meeting	3/5/2021	Bob Jaques	Of the various approaches you've described here, is there any estimate of the amount of pumping reduction that would curb under those various scenarios to the sustainable yield? Is there anything other than pumping allocations that has a chance to close that gap?	Abby Ostovar: You mean projects?	Meeting comment - noted.
204					Meeting	3/5/2021	Bob Jaques	Other than simply requiring pumping to be reduced, do any of the other things you mentioned achieve the reduction needed to get to sustainable yield?	Abby Ostovar: Good question. We're talking about the magnitude being over 1,000 AF being reduced. Without the new projects mentioned today, these projects are much smaller than the overdraft. It's looking like allocations may be needed. Everybody could cut the same amount. We haven't done what the volumetric cut down would be, I wanted to keep this conversation conceptual. We would also need to consider a minimum for the human right to water per person to have. We haven't done that analysis.	Meeting comment - noted.
205					Meeting	3/5/2021	Bob Jaques	As you mentioned, if you add those project benefits together, it probably wouldn't be a real big number. Requiring reductions in pumping is going to be the path you need to take to get to sustainable yield. And should be included as a probable thing that has to be done.	Abby Ostovar: I understand this is extremely uncomfortable for everyone, but with the GSP we have to show DWR that we can locally manage our groundwater so that the state doesn't come in and do it.	Meeting comment - noted.
206					Meeting	3/5/2021	Janet Brennan	There's a significant emphasis that the allocation structure is not related to groundwater rights, making the distinction. Yet Option 1 is based on overlying rights. Isn't that a contradiction?	Abby Ostovar: It's tricky. We're trying to avoid an adjudication. No one is going to be fully happy, but how do we prevent someone being so unhappy they start an adjudication? It's a really challenging subbasin. We tried to bring you the main options.	Meeting comment - noted.
207					Meeting	3/5/2021	Margaret-Ann Coppernall	I have a question about the notification if wells would go dry. Do you have any data on which wells went dry in the past and what caused them to go dry? I think it's important to avoid crisis management.	Abby Ostovar: We don't know exactly which wells went dry, no one is collecting that data. The closest we came is developing a groundwater contour, and then looking at the depths of wells that have been drilled. We talked about this when we talked about the SMC. There aren't too many wells we could assess accurately because their location information is not accurate. The analysis is based on the depth of the well and the contours, and determining which wells may go dry.	Meeting comment - noted.
208					Meeting	3/5/2021	Margaret-Ann Coppernall	I think we need to include climate change and sea level rise in the analysis.	Abby Ostovar: We are working on developing future sustainable yield which will take into account climate change. When we finish the water budget, it will include that.	Meeting comment - noted.
209					Meeting	3/5/2021	Beverly Bean	The wells that did go dry and caused the B8 moratorium, the wells most likely to go dry are in the B8 zone. It's my impression the *de minimis* users with their own wells that use huge amounts of water on their various activities would not be affected by these allocations. They will continue to use all the water they want.	Abby Ostovar: While the GSA cannot require metering from various users less than 2AF, they can be regulated. The GSA could implement a pumping charge. There are ways they can somewhat be included, there is some ability. Sarah Hardgrave: I found Table 2 in the Wallace Group memo, on Page 56 of the full agenda packet. It has a list of all municipal systems. I appreciated the data provided today. It showed me that there are 312 private non-agriculture wells, and their total use was not as big as I thought it might be.	Meeting comment - noted.

210					Meeting	3/5/2021	Christopher Bunn	As far as metering, I hope we can meter as many entities as possible. With more data, we can have a more honest discussion. As far as irrigated acreage, you have 1027 irrigated acres and you only have 408 AFY for water use. For sake of discussion, an acre of romaine will take 1 AF. You have to check and see where those ranchers are pumping, if it's within the subbasin or just next door in the 180/400. Romaine is the least thirsty of the crops. It's	Abby Ostovar: Given that GEMs cover most agriculture areas, we should be able to use that data for an analysis for water used. We haven't done an analysis about whether someone is pumping from outside the subbasin and bringing it in. Sarah Hardgrave: The table on Page 57 of the report, the note says it was based on lettuce and romaine.	Meeting comment - noted.
211					Meeting	3/5/2021	Beverly Bean	I just want to clarify that this meeting would be to discuss allocations, projects, and the numbers you need from us. I want clarification on what this meeting would be about.	Sarah Hardgrave: We have not provided feedback on projects or pumping allocations options. And we need to discuss the SMCs. Have a more focused conversation that we haven't really been able to do today. Abby Ostovar: The other part of Beverly's point is that we haven't prepared the water budget with EKI. We will get that to you as soon as possible, but it isn't ready yet.	Meeting comment - noted.
212					Meeting	3/5/2021	Sarah Hardgrave	We need to look for about 1,000 AF of either additional water supply projects or supplemental sources, combined with reductions of pumping to achieve sustainability.	Abby Ostovar: That's our best estimate now. We will do full analysis but we'll refine numbers as best we can. It's on the right order of magnitude.	Meeting comment - noted.
218					Special Meeting	3/23/2021	Sarah Hardgrave	It would be helpful to know how many wells will be impacted at each Measurable Objective.	Emily Gardner: I don't have the answer either. We always talk about these plans being pretty iterative. We talk about the Minimum Threshold and Measurable Objective as relatively solid. This has me thinking, say we pick the lowest one, achieve it, and realize there are some wells that have problems, could we then strive to go higher? Abby, do you know anyone doing that? Abby Ostovar: No, but we do have the 5-year update. We can do the data analysis with the data we have. We can do the analysis, but won't be very helpful since so many wells are not shown at their accurate locations.	Meeting comment - noted.
219					Special Meeting	3/23/2021	Gary Kreeger	The Minimum Threshold, 2015, that was in the middle of the big drought? How much of that level was from the drought? How much was from over pumping? If you are picking a drought year, you are picking pretty rock bottom.	Abby Ostovar: We can say that the trend is going down, regardless of drought year. But they both have an impact. It's hard to separate them out. Here, it went lower in 2016, and 2019 was slightly below 2015 levels. DW: It's hard to disaggregate when we already have declining water levels. The drought is overlain on a significant downward trend. Our bigger concern is the ongoing depletion here.	Meeting comment - noted.
220					Special Meeting	3/23/2021	James Sang	I notice already we're below the Minimum Threshold, are you saying we already have to start conserving water? Is there any benefit if the water level goes above the Measurable Objective?	Abby Ostovar: Regardless of being below the Minimum Threshold, you need to still have actions to get to the MO. The lower you are, the harder you have to work to get there. While there are benefits to being higher than the Measurable Objective, so until that happens, I can't quite say.	Meeting comment - noted.
221					Special Meeting	3/23/2021	Christopher Bunn	I think as part of this discussion, I would want to see what the interaction is between the Toro Aquifer and the aquifers of the 180/400. Because unless that's modelled, you're not going to know what the pumping in that basin is really going to be doing and how it will influence this subbasin. I think that's a pretty important part of the puzzle. Now that the model is available, you can run that analysis.	Abby Ostovar: We've mapped the groundwater elevations and we've looked at how the aquifer contours fit together. Our modelers from M&A are working with EKI modelers, and looking specifically at those cross-boundary flows. They're deep in the modeling world trying to figure that out.	Meeting comment - noted.
222					Special Meeting	3/23/2021	Christopher Bunn	Are you going to look at the historical influence of other subbasins? What did pumping outside of the Monterey Subbasin do to the historical decline?	Abby Ostovar: The SVIHM goes back to 1967 or so, but only has one calibration point in the Monterey subbasin. The EKI model goes back to 1998 and the model run is from 2003 to 2018. Those are the time frames where we'll have a good assessment of this.	Meeting comment - noted.
223					Special Meeting	3/23/2021	Bob Jaques	If you reduce your pumping to a sustainable level, your decline would stop but it wouldn't raise the level any higher to where you flattened out. In the Seaside Basin, we're seeing that meeting the sustainable pumping level doesn't make up for the overpumping that occured prier to that. That is something that should be discussed here. If you want to get higher than 2015, you have to look at how to further reduce pumping below the sustainable level or import another source of recharge water.	Comment received.	Meeting comment - noted.
224					Special Meeting	3/23/2021	Ron Stefani	Re: Measurable Objective for groundwater levels: I think we should go with the lowest one. When we get into project costs, as we move up the level, it will get more expensive. I believe it will be cost related.	Abby Ostovar: Excellent point. I will point out these aren't the only options, you can benchmark any year.	Meeting comment - noted.
225					Special Meeting	3/23/2021	Sarah Hardgrave	I would tend to agree. I think we should strive toward something that may be more achievable in the near-term, and see what we can accomplish in the first 5 to 10 years.	Comment received.	Meeting comment - noted.

226					Special Meeting	3/23/2021	Bob Jaques	I'm kind of jumping ahead to projects, just looking at this chart again, if you pick the lowest of the 3 proposed Measurable Objectives, which is 2011, and your 2015 level is that 8 feet below that, and it will go more below before we get to management activities and projects, in the list of projects and management activities under discussion, they all seem targeted at achieving sustainable yield level. That won't meet your objective of raising the groundwater level objective. I think we need to look beyond sustainable yield. We need to look at bringing the groundwater level up, and then maintain sustainability.	Comment received.	Meeting comment - noted.
227					Special Meeting	3/23/2021	Margaret Anne Coppernall	I want to say that I agree with the two speakers who mention the cost. I think it would be helpful to know the cost before we make a decision to compare the cost and affordability. I think the groundwater level is very important, especially with relation to seawater intrusion and taking into considering sea level rise.	Comment received.	Meeting comment - noted.
228					Special Meeting	3/23/2021	Janet Brennan	We have a recommendation of 8 feet and 16 feet, why don't we compromise at 11?	Comment received.	Meeting comment - noted.
229					Special Meeting	3/23/2021	Patrick Breen	Do we have any sense of pump depths and if anything went dry in 2016?	Abby Ostovar: We don't. We have the domestic well analysis where we looked at the depths of wells and water levels. We did it for 2015 levels, but we don't have the accurate locations for the wells, it's only a sampling of them. We could do the same analysis for 2016.	Meeting comment - noted.
230					Special Meeting	3/23/2021	Gary Kreeger	I understand there are difficult decisions to make. If you go above that 8 feet and shoot for 11, it will be a little more work, but it will give you a little more cushion.	Comment received.	Meeting comment - noted.
231					Special Meeting	3/23/2021	Beverly Bean	It troubles me to understand how much about these water levels are projections and estimates and modeling numbers, and how few are actual real numbers from actual wells. The GeoSyntec report recommended more test wells to get a better picture and I don't think that happened. We're not collecting data to make these decisions. How much of what you're recommending is based on actual data from those wells? I don't think we're getting enough real data. The other thing that troubles me is one of the management actions we need to look at is reducing pumping. How are we going to do that? We don't have enough well data, can we do something about getting more well data?	Abby Ostovar: This is based on actual groundwater well data. The domestic well analysis was projected/extrapolated between the monitoring wells. The domestic well analysis was more an estimate based on the depths of the wells versus this is based on actual monitoring data. However, you can include in the implementation actions installing more monitoring wells which could help with management down the road.	Meeting comment - noted.
232					Special Meeting	3/23/2021	Beverly Bean	Are you satisfied with this data, do you think it's enough to make these decisions?	Abby Ostovar: I never think there is enough data, but we have to use what we have.	Meeting comment - noted.
233					Special Meeting	3/23/2021	James Sang	I want to see that Minimum Threshold lowered. Are you planning on telling stakeholders that they have to cut off their water supply? We have to implement these ideas before we do anything? This puts a lot of stress on stakeholders.	Comment received.	Meeting comment - noted.
234					Special Meeting	3/23/2021	Gary Kreeger	I would be hesitant to push the Minimum Threshold lower. We are already overpumping. I agree with Beverly, at some point we have to talk about restrictions on pumping.	Comment received.	Meeting comment - noted.
235					Special Meeting	3/23/2021	Janet Brennan	Recommend a Measurable Objective at the 2008 groundwater level.	Motion passed unanimously.	Will be incorporated into SMCs.
236					Special Meeting	3/23/2021	Sarah Hardgrave	The steep decline is pretty alarming, to see 5 feet from one year to the next. A drop of 30 feet over a 16-year period is very concerning. I would concur with Mr. Jacques to see about having projects that would increase the levels over time. This is a really difficult situation for this area of the subbasin. I do hope that in addition to the projects, that we will also be able to think big picture as well.	Comment received.	Meeting comment - noted.
237					Special Meeting	3/23/2021	Beverly Bean	Does the chart include getting the golf course off potable water for their greens?	Abby Ostovar: In the in-lieu projects, this was a program to incentivize alternative sources instead of pumping. The approach we're trying to take is to not tell specific actors what to do, but we can look at that.	Meeting comment - noted.
238					Special Meeting	3/23/2021	Beverly Bean	On the peninsula during restrictions, there was a moratorium on new hookups. Are restrictions or moratoriums on new hookups on the table? We should be making recommendations to those who do have the power to do so.	Abby Ostovar: We have to work within the authority of the GSA. So we'd have to work in partnership with the County. It might be helpful for future planning development but we need to have a conversation with the County. It won't address existing water use.	Meeting comment - noted.
239					Special Meeting	3/23/2021	Sarah Hardgrave	The Corral de Tierra golf course is not located in close proximity to a sewer system that would be able to recycle water for irrigation. I think that's why it wasn't identified in the list of projects before us. Because the WW facilities are not nearby.	Abby Ostovar: Yes, these WW facilities are near the boundary with the 180/400.	Meeting comment - noted.

240					Special Meeting	3/23/2021	Sarah Hardgrave	In the example of the cease and desist order, it deals with a different circumstance. I think the question that we should ask the staff and consultants to explore is how do that findings of this analysis and ID of overdraft through the GSP, how will the County determine the safe and adequate water supply for new development? How will the county use the GSP to inform their decisions? It is a worthy conversation to have with the County Department of Environmenal Health.	Comment received.	Meeting comment - noted.
241					Special Meeting	3/23/2021	Janet Brennan	Using pumping allocations and control, in essence, will result in in-lieu projects because those are the options available to reduce pumping. It seems to me through an allocations system you could limit new developments by not allocating water to vacant parcels, or limiting the amount of water for vacant parcels, which would be a way to address new development. How difficult will it be to implement pumping allocations?	Abby Ostovar: Developing an allocation structure will be challenging, but it can be done. The goal of it could be to avoid adjudication, which is also a lengthy process. One of the challenging parts in this area will be to figure out how to deal with *de minimis* users. There will be some steps, the MCWRA only collects extraction from a portion of the subbasin. There will be various steps in collecting the data. It's not outside of the realm of what's doable.	Meeting comment - noted.
242					Special Meeting	3/23/2021	Janet Brennan	Table 2, 3,542 connections that could be affected by allocations. In Salinas Hills (0.73 AFY), Corral Estates (0.75 AFY), Robly (0.75 AFY), I mean these are huge water demand figures, especially when you compare to the peninsula.	Comment received.	Meeting comment - noted.
243					Special Meeting	3/23/2021	Bob Jaques	I support Beverly's comments. I think that in the projects, it would be good to add a few more. One could be use recycle water for landscape and golf course. Another could be about limiting or halting new connections. It may be infeasible, but for anyone reading the GSP, if they're not in there, someone might think it wasn't considered as a management action.	Comment received.	Meeting comment - noted.
244					Special Meeting	3/23/2021	Sarah Hardgrave	You've done this analysis of cost, is that a requirement of the GSP? Can you have a project without a cost associated with it?	Abby Ostovar: You don't need a cost, you just need to show you've considered projects and management actions and lay out a path forward. This is mainly for us and our stakeholders to understand the level of effort and which projects to prioritize.	Meeting comment - noted.
245					Special Meeting	3/23/2021	Sarah Hardgrave	I agree with both Bob and Bev on those potential additions.	Comment received.	Meeting comment - noted.
246					Special Meeting	3/23/2021	Bob Jaques	I see a mention of a "direct potable" use and I assume you mean indirect potable use.	Comment received.	Meeting comment - noted.
247					Special Meeting	3/23/2021	Sarah Hardgrave	Re: WW going to Marina. I think the challenge for our management area, if we're sending that water up to be treated, how do we get it back to be used here. I'm not sure how that can come back to this area, except for a pipeline to bring it back.	Abby Ostovar: Our subcontractor talked about increasing the level of treatment at the existing facility. She has a much better handle on the most feasible option and she will scope that. We solicited ideas in November and December. We can add these two new projects, but we need to have this chapter done in the next month.	Meeting comment - noted.
248					Special Meeting	3/23/2021	Margaret Anne Coppernall	Given the steep drop in groundwater level, we need to have a sustainable supply for people who are already existing, who already need it, not new development.	Comment received.	Meeting comment - noted.
249					Special Meeting	3/23/2021	Gary Kreeger	I'd like to know more about the linkage between the authority for approving development and our authority around water. I think there should be no more new development included [in the GSP] to reinforce the idea there's a real problem here. We're talking about allocation controls, do we have the authority to tell people to stop pumping as much? Can we cut back? How do we enforce that?	Sarah Hardgrave: There was a workshop provided for all subbasins on allocations. It is posted on the SVBGSA website.	Meeting comment - noted.
250					Special Meeting	3/23/2021	Sarah Hardgrave	My observation of the proposed projects is that they are costly, complicated to implement, but they are the choices we've got. My biggest concern is that they may not be enough to get to sustainability. That is the challenge in this area. It seems like we need to include all of these options and make an effort for all of these options. But also look outside of this area and look to a regional effort to achieve sustainability. I'm concerned about the declining water levels in the Laguna Seca area. Also, the comment from Mr. Bunn earlier about how are we being affected with what is happening in the 180/400. How can we adjust sustainability in this area working with our adjacent subbasins for potential regional solutions?	Comment received.	Meeting comment - noted.

251					Special Meeting	3/23/2021	Christopher Bunn	Some of the solutions lie outside of your subbasin and that is why the modeling is so crucial. The multi-benefit stream channel could potentially benefit you guys significantly. It could reduce agricultural pumping in the 180/400, which could impact this subbasins well levels. However, the way that project is presented, it's going to fail. Right now it is being presented where the GSA is covering the cost of administration, but you also have the cost of doing the work. It's a 95-mile river, but the final 10 miles can't be worked on. 85 miles and many land owners are absentee, and won't spend the money. That project needs to be done on the whole river and needs to be tweaked. I'd love to see the modeling to see the effects on this subbasin.	Comment received.	Meeting comment - noted.
252					Special Meeting	3/23/2021	James Sang	I'd like to suggest a project only for well owners. I want to see this group suggest to well owners to build infiltrating trenches around their wells to recharge their own wells. Trench 2 feet deep to prevent rainwater from being evaporated. This could be a huge amount of water to recharge their wells.	Sarah Hardgrave: We do have the decentralized stormwater project, which is similar to what you're suggesting. It is a very expensive endeavor for not as much water as we would like.	Meeting comment - noted.
253					Special Meeting	3/23/2021	Sarah Hardgrave	We encourage SVBGSA, EKI and MCWD to think about potential opportunities for projects that would benefit both management areas for the subbasin and also how to coordinate any potential allocation program across both management areas.	Comment received.	Meeting comment - noted.
254					Special Meeting	3/23/2021	Janet Brennan	I'm torn between Option 2 and 3. From a policy perspective, it seems drinking water systems should be a priority. But Option 3 maintains the existing proportion of use.	Comment received.	Meeting comment - noted.
255					Special Meeting	3/23/2021	Beverly Bean	I'm favoring Option 3, it seems like it treats all water users pretty equally. If we prioritize one group over another, we're inviting lawsuits and people who would feel unhappy and unprioritized. Back to my point about a moratorium, if that large precent of users are in a large system, I think the idea of some form of a moratorium would be possible. I think we should consider that when we make these decisions.	Comment received.	Meeting comment - noted.
256					Special Meeting	3/23/2021	Beverly Bean	I think the best way to do it is to treat everyone as equally as possible. Everyone should share the pain.	Comment received.	Meeting comment - noted.
257					Special Meeting	3/23/2021	Margaret Ann Coppernall	I agree and lean towards Option 3. We need to be fair. I know senior overliers will protest if they don't get their fair share. I agree we need to pick the option that is the fairest to everybody.	Abby Ostovar: More analysis will happen, and we'll have to deal with outliers. You're at the right level of thinking.	Meeting comment - noted.
258					Special Meeting	3/23/2021	Sarah Hardgrave	I am also leaning toward Option 3. Sounds like we have a majority of folks leaning in that direction. I would welcome a motion. One question, Abby, we need to achieve sustainability in the entire subbasin. I'm wondering if the discussion of allocations needs to include the Marina-Ord area? Could you work with our other management area on that question?	Abby Ostovar: Groundwater law is still evolving, we're figuring out where the courts are on this issue. Having the Ord area in the middle and separate management areas and different principal aquifers makes this difficult. Patrick Breen: In all our area, we're the only pumper. If there was a reduction on pumping in the area, it would just be us. If we're not sustainable, the reductions would be born solely on the water district, so we don't really have this equity issue.	Meeting comment - noted.
259					Special Meeting	3/23/2021	Janet Brennan	I recommend Option 3 for the allocation system.	Motion passed. Bob Jacques abstained.	Option 3 for a pumping allocation description will be included in the GSP.
260					Special Meeting	3/23/2021	Margaret Anne Coppernall	A topic that came up earlier, about Pure Water Monterey Project that is looking at expansion this week. Looking at FEIR. Is there a way to coordinate with them on a cost analysis for a pipeline to bring recycled water over here in the future?	Sarah Hardgrave: This will be included in the additional projects that will be scoped.	Meeting comment - noted.
261					Special Meeting	3/23/2021	Bob Jaques	Abby, when you're going through the projects slide, there was the topic of prioritizing listed in the packet, or talked about it. I didn't hear any conclusions or consensus about prioritizing. Is that something this group needs to come up with?	Abby Ostovar: You don't have to, but it would be helpful to us if you did. Now would be a great time to do that to include in the chapters.	Meeting comment - noted.

262					Special Meeting	3/23/2021	Bob Jaques	From our perspective, we're concerned about the effects of pumping and the dropping water levels. The modeling shows that the Corral de Tierra pumping is causing the Laguna Seca levels to fall. When you look at the cumulative amount of pumping reductions versus the projects, you need to cut it down by about 1000 AFY. The total amount of the other projects only add up to about 400 AF. It's obvious pumping reductions/allocations will have to be imposed. I think it should rise to the top as one of the most critical choices. I think it should be one of the high priority projects in the GSP.	Comment received.	Meeting comment - noted.
263					Special Meeting	3/23/2021	Beverly Bean	I completely agree with Bob, and I would like to put that forward as a motion. Let's not waste any more time with costly schemes, let's get this pumping down. Motion: Pumping allocations should be our top priority.	Motion passes unanimously.	Prioritization of pumping allocations will be incorporated into the GSP.
264					Special Meeting	3/23/2021	Margaret Anne Coppernall	I think it's a very prudent motion.	Comment received.	Meeting comment - noted.
265					Special Meeting	3/23/2021	Janet Brennan	I agree with the motion.	Comment received.	Meeting comment - noted.
266					Special Meeting	3/23/2021	Marieke Desmond	I appreciate the committee so carefully considering these options. Equity in water will depend on how accurately we measure it. We encourage metering in these allocations discussions.	Comment received.	Meeting comment - noted.
267					Special Meeting	3/23/2021	Marieke Desmond	It's so important to get to the sustainable yield on this issue, but I want the committee to keep looking at supply solutions as well as pumping allocations. Pumping allocations alone aren't necessarily the key to sustainability although they can help get to a better water storage levels.	Sarah Hardgrave: Yes, to clarify, I wasn't saying that we shouldn't pursue any of the projects. It is helpful to have allocation prioritized as an initial action in addition to the projects that were laid out because they won't get us to sustainability by themselves.	Meeting comment - noted.
268					Email	4/12/2021	James Sang	I wanted to present some potential agenda items.	Comment received.	Point #1 was considered throughout the Salinas Valley and it is incorporated in projects for other Subbasins.
								1. Can rainfall harvesting through swales refill wells and increase groundwater and water aquifers?		
								Reference a: You Tube video (Harvesting Water Naturally with Swales by Urban Farmer Curtis Stone)		Point #2 has been incorporated into the overland flow MAR project which was modeled on the Pajaro Valley project noted.
								Reference b: You Tube video (Recharging A Well Part II -John Kaisner The Natural Farmer)		
								Reference c: You Tube video (Swales on Contour can Drought -proof Gardens, Farms and Pastures with Water Harvested Passively by Edible Forest Gardens)		
								Reference d: You Tube Video (Deep Soil Ripping for Water Conservation by Megan Clayton)		
								Reference e: "Deep Soil Ripping as an Effective and Affordable Water Capture Tool written by Amanda C. Krause, Megan K. Clayton, ...et al" Please google search article.		
								2. Can you make a presentation on what UC Santa Cruz is doing to recharge their wells? This is what Robin Lee wanted.		
								Reference a. You Tube video (Enhancing Groundwater Recharge in the Pajaro Valley by California Department of Food and Agriculture)		
								I believe that swales and subsoil plowing can recharge a farmers well, groundwater and aquifers. This is a cheap and easy way to help every farmer and landowner have a plentiful supply of water. This idea will solve California's goals of recharging water aquifers and holding back salt water intrusion into our coastal lands.		
								Can you show this to all interested parties?		

269	4				JotForm	4/22/2021	Ron Weitzman	I am objecting to the claim by the Hydrogeological Working Group in their letter of 5 April 2021 that your designation of the Dune Sand Aquifer as a Principal Aquifer is incorrect. While the EIR for the Monterey Peninsula Water Supply Project, for which HWG has consulted, dismally failed to model that aquifer successfully, with a relative error equal to 30, it has reported that it may account for up to two-thirds of the source water for the project. According to Appendix E2 of the 2017 and final EIR (p. 28), "The third approach used reported results that determined the pumping allocation based on well-screen configuration and model calibration to the test-slant-well pumping results (66% from Model Layer 2 and 34% from Model Layor 4)." That alone qualifies the DSA as a Principal Aquifer. Other reasons supporting that designation also exist. According to the hydrogeologist hired by Water Plus, Barbara Ford, "The extremely low Kv applied to the Dune Sand/A Aquifer unit [in the EIR], and particularly in the underlying layer 3, appears to have resulted in eventually reducing the residual at three of the wells. The extremely low Kv was applied to reduce the residuals at the wells, but because the value seems unreasonable, its use as a mechanism (prop up the head in layer 2) to improve the appearance of the calibration, instead reduces the confidence in the calibration." That contrived low kv makes the Dune Sand Aquifer incorrectly appear to drain little or no water from overlying streams, ponds, and the Salinas River. According to the hydrogeologist hired by the California Coastal Commission, no evidence exists to support that claim and, in fact, evidence shows that aquifer has a seaward gradient, which could allow seawater intrusion only if MPWSP wells draw water from it. The Dune Sand Aquifer is indeed a Principal Aquifer, as your Groundwater Sustainability Plan currently asserts.	Comment received.	The Dune Sand Aquifer is included in the GSP as a Principal Aquifer. Chapter 4 describes it further.
270	1, 3, 4, and 5			Figure 5-1 through 5-10	Email	4/23/2021	MCWRA	Some sections are not completed or indicate future revisions and updates. MCWRA looks forward to an opportunity to comment on those when completed. Suggest that on the Figures that combine the Lower 180-Ft Aquifer and the 400-Ft Aquifer wells, they be symbolized differently. Suggest adding FO-11, along with FO-09 and FO-10 wells, to the monitoring network. On Figures 5-1 through 5-10, suggest changing the color of the dot to something other than black. It is difficult to see the locations when they are close to the black/white dashed boundary lines.	Comment received.	Wells FO-10 and FO-11 are included in the monitoroing network. Additional wells will be added to the monitoring network during Implementation.

271	7				Email	5/27/2021	MCWRA	Appendices mentioned in the text were not provide so MCWRA staff were unable to review.	Comment received.	There are multiple tables accross chapters 5, 7, and 8 that detail the constituents that occur in the groundwater and in tested drinking water systems, as well as the regularity of water quality reporting for these constituents.
								Suggest adding a table that clearly list which analytes and parameter are being collected/measured, including frequency and methodology (i.e. lab analyzed or field measurements w/ hand-held instruments)		Seawater intrusion monitoring will occur in wells with records of either Chloride or TDS as described in Chapter 7. Chloride is prefered, however, TDS will supplement to increase spatial distribution of SWI monitoring. These details are described further in Sections 5.3 and 7.5.
								For seawater intrusion monitoring, suggest clearer description…will chloride concentration be used, or TDS, or conductivity?		
								MCWRA has provided other minor and/or editorial comments on the chapter of the Draft GSP to Montgomery & Associates in a Word document that was supplied for that purpose		
272					Meeting	5/7/2021	John Bramers	I was going to mention on the outreach that it's deceiving in the way it's called. It's Toro Park, San Benancio, etc.….The stakeholders out there hear "Monterey" and don't think they are a part of it.	Donna Meyers: If you think we may know or have contact, but if you have direct contact with them, we'll cross-reference them. We want to make sure we have a completed group. We'll have an outline of how to approach this and any dates. We'll be planning that in the next several weeks and will get you that information, including dates we're striving for.	Meeting comment - noted.
									Sarah Hardgrave: I would welcome any committee members who have contacts at HOAs to please share those with us and I will cross reference them with our District contacts.	
273					Meeting	5/7/2021	Gary Kreeger	Regarding using different models, could you speak to how understanding how our subbasin will interact with others since we know they're all connected?	Derrik Williams: The modeler who is putting this together now, as he is finalizing it, is to make sure the interaction with the other subbasins is well simulated. The model is going to be developed to have an accurate representation across the boundaries. The only thing that will come up will be how we simulate projects in other subbasins. Say, the impact on the 180/400, we'll have to roll it into this model and it is an extra step. If water levels are going up in the 180/400, how will it affect this subbasin? I don't think it's going to be a difficulty, just an extra step. I don't think there will be any inaccuracies.	Meeting comment - noted.

274					Meeting	5/7/2021	Bob Jaques	Agenda makes a brief mention about a seawater intrusion model to be funded with grant funds. How far into the adjacent basins will the model go? I'm interested in it if it will extend into the Seaside subbasin.	Derrik Williams: First plan is to develop the model only for the Monterey Subbasin. Then we will extend it into the 180/400. We want to pick up all seawater intrusion observed. There isn't any seawater intrusion observed in the Seaside subbasin, so it's not in the plan right now. But if we start see that, we will develop a plan on how to extend that.	Meeting comment - noted.
275					Meeting	5/7/2021	Tamara Voss	Just to tag on to Bob's comments and interest in the potential seawater intrusion in the Seaside area, I think Derrik, you're correct that we're not seeing seawater intrusion in the Paso and Santa Margarita aquifers. I do think there is evidence of seawater intrusion in the shallower aquifers, which can then migrate down. The aquifers of use and interest don't have seawater intrusion, but there is high chloride level water in the shallower water that can move vertically down, and this group should not lose track of that mechanism.	Derrik Williams: Point well taken, thank you, Tam.	Meeting comment - noted.
276					Meeting	5/7/2021	Sarah Hardgrave	The recent annual seawater intrusion monitoring included some indicator findings at a recent meeting with the Seaside Watermaster, and I concur with that. I'm glad to hear we're not in a situation of dueling models. There seems to be good agreement on using this model in-lieu of the SVIHM model. Are they using different software platforms? Are they completely separate approaches? Or are they similar based software for the modeling?	Derrik Williams: They are similar software packages, but not identical packages. The fact that they're similar makes it easier to transfer information between the two. The fact that they're different is why the Monterey model will be better for seawater intrusion. They're both based on codes developed by the United States Geological Survey.	Meeting comment - noted.
277					Meeting	5/7/2021	John Bramers	To follow up on that, for the area on Reservation Rd, will that area be managed with the 180/400?	Donna Meyers: That is still planned to be managed as part of the Corral. We would have to do a boundary adjustment. Abby Ostovar: We've thought about a boundary adjustment. It's a complicated process that takes a lot of time. We're just trying to be more explicit in the GSP so it's not just lumped into the Marina Ord management area. They do have a monitoring network closer to those areas.	Meeting comment - noted.
278					Meeting	5/7/2021	John Bramers	I'm confident most of the water in those farming areas is coming from the 180/400. It's going to be a challenge for projects.	Abby Ostovar: That's how we arrived here. As we have gone further in the GSP process, these flags have come up.	Meeting comment - noted.
279					Meeting	5/7/2021	Sarah Hardgrave	One of those areas is the Bluffs Development, the sort of southern one. The other ones are more on the valley floor and in agricultural use. And then there's the one little triangle, also agricultural use?	Abby Ostovar: Strawberries	Meeting comment - noted.
280					Meeting	5/7/2021	Sarah Hardgrave	In terms of the name, referring to it as Reservation Road area makes sense to me. Seem intuitive. Does anyone have other suggestions? Let's go ahead and go with that, as a way to call it out. Will there be some slightly different management actions for those areas that would be more along the lines of the management actions in the 180/400?	Abby Ostovar: Actually, yes, you'll see that in the next slides with regional projects. Benefit assessments will be done. We've widened our scope on projects and management actions.	Meeting comment - noted.
281					Meeting	5/7/2021	Janet Brennan	Relating to the extraction barrier project, to address seawater intrusion. In listing your projects, it only talks about using the water for desalination. It doesn't address the seawater intrusion project specifically. My suggestion is that to be included, specifically. Why is that project not included in the MCWD's proposal to address seawater intrusion in that area?	Patrick Breen: Participation in regional projects is at a conceptual level, MCWD would entertain participating in the regional projects. We have not cited it for the MCWD GSP because it is at the conceptual level. We're not opposed to it.	Meeting comment - noted.
282					Meeting	5/7/2021	Janet Brennan	I suggest you include it in the regional projects.	Abby Ostovar: We're still working through how we develop the partnerships and support. Yes. We'll figure out how to have it in there.	Meeting comment - noted.
283					Meeting	5/7/2021	Janet Brennan	I also have a recommendation for another project for the Corral area. Specifically request the County of Monterey expand the B8 planning area for land use.	Abby Ostovar: That has been brought up previously, thank you for flagging it.	Meeting comment - noted.
284					Meeting	5/7/2021	Sarah Hardgrave	One comment about invasive species eradication, you're talking about the unit cost for remaining work. I don't think invasive species eradication ever ends as it requires ongoing effort.	Abby Ostovar: We've been working with Resource Conservation District of Monterey County (RCDMC) on this, it includes the remaining acres along the Salinas River. The idea is the full 900 acres are treated in a timely manner, with retreatments along the way. What his number doesn't include is if you don't treat it, how arundo will spread.	Meeting comment - noted.
285					Meeting	5/7/2021	Sarah Hardgrave	Will the recharge basins be located in the 180/400? Where are they located?	Abby Ostovar: We don't have locations. This is a notional cost.	Meeting comment - noted.
286					Meeting	5/7/2021	Sarah Hardgrave	To clarify, that is the number for within our planning area? Or for the 180/400?	Abby Ostovar: We had it scoped out for what the 100-acre basin would cost. This number is not realistic for the Monterey subbasin, we have to think a little more carefully about how it would fit here.	Meeting comment - noted.
287					Meeting	5/7/2021	Bob Jaques	What recycling plant are you referring to for the source?	Abby Ostovar: Cal Utilities Service plant.	Meeting comment - noted.

288					Meeting	5/7/2021	Bob Jaques	That's the one right by the Salinas River, off Reservation Road. Was there any investigation into the Las Palmas plant? I know they have surplus water at certain times of the year.	Abby Ostovar: They already put a lot of that water to use in medians and open spaces. The two big things going in are it's costly to go in and costly to pipe it somewhere.	Meeting comment - noted.
289					Meeting	5/7/2021	Tom Adcock	I am on the GSA board at this time, representing a utility, Alco Water Service. My comments don't have anything to do with the GSA board. I am also the general manager for the Cal Utility Service. It's located at the confluence of Toro Creek and the Salinas River. We have ~130 acres of spray field to put secondarily treated wastewater, near the river. I would be happy to work with the GSA or subcommittee or engineering firm to discuss the ability to provide reclaimed wastewater to where our customers are. There's no doubt that it costs a lot to build pipes and transport water. The estimate seems a little high. I think there are ways to place distribution mains to bring that cost down significantly. Very happy to answer any questions. I want to make sure the agency understood Cal US is happy to work with you.	Comment received.	Meeting comment - noted.
290					Meeting	5/7/2021	Sarah Hardgrave	I was involved with early planning and feasibility and design of the Pacific Grove local water project, which provides recycled water to the PG golf course. That's a small package plant that's in operation. It might be a good reference point. I think Wallace Group would have that information.	Abby Ostovar: Piping is a large part of the cost. We didn't see anywhere else to bring the water. We can get together with Mr. Adcock and see where else we could look. Sarah Hardgrave: The primary place of use is the Corral de Tierra Golf Course.	Meeting comment - noted.
291					Meeting	5/7/2021	Margaret Anne Coppernall	I was curious about the rollout for the seawater intrusion extraction portion discussed earlier. I was wondering where it was going to be placed and how it would function.	Sarah Hardgrave: My understanding is that this was identified in the 180/400 plan that was submitted to the Department of Water Resources in 2020. Abby Ostovar: Right now it's a conceptual idea, it is not at the stage for planning or a feasibility study. It hasn't progressed to where we're taking implementation steps.	Meeting comment - noted.
292					Meeting	5/7/2021	Sarah Hardgrave	It's effectively the Highway 1 corridor north of the river?	Derrik Williams: Conceptually, it was placed along Highway 1, north of the river. Conceptually, because it does give us a line that covers the entire basin and protecting most of the municipalities. It will probably change going forward, but conceptually that's the right place.	Meeting comment - noted.
293					Meeting	5/7/2021	Janet Brennan	I would like to ask the committee to consider to ask the County to expand B8 as a recommended program. I would like consideration of that.	Comment received.	Meeting comment - noted.
294					Meeting	5/7/2021	Sarah Hardgrave	I appreciate the project to take brackish water, desalinate it and use it to provide an additional source of water, and the multiple benefits it would produce. I'd like to reiterate my support for a publically owned project for a more affordable supply.	Comment received.	Meeting comment - noted.
295					Meeting	5/7/2021	Beverly Bean	I would support what Janet is saying, I just wonder where it would expand to. Would you base it on the previous study or look at new numbers? Planners and the county don't even enforce it, or know what it is. The county just approved a subdivision, even though the Land Use Advisory Committees (LUAC) pointed out that it was in the B8.	Comment received.	Meeting comment - noted.
296					Meeting	5/7/2021	Janet Brennan	The B8 should be updated to reflect current overdraft conditions, and that the county enforce its B8 zoning.	Comment received.	Meeting comment - noted.
297					Meeting	5/7/2021	Margaret Anne Coppernall	I support if it means getting more information, if it's feasible.	Comment received.	Meeting comment - noted.
298					Meeting	5/7/2021	John Bramers	This is getting into land use. You probably need more information before you vote on it.	Comment received.	Meeting comment - noted.
299					Meeting	5/7/2021	Sarah Hardgrave	It is unclear to me at this time the relationship between our water planning efforts and the land use side of things. It would be helpful to have a better understanding. I'm not disagreeing with Janet's suggestion. It could be an important measure for not intensifying or adding use in the subbasin. It is unclear to me how the GSP recommendations for land use actions would be received on the County side.	Comment received.	Meeting comment - noted.
300					Meeting	5/7/2021	Janet Brennan	The GSA has no land use authority. Under an allocations system, which does not affect water rights, has an effect on land use indirectly. I have no problem with the GSP addressing this more directly. Because the projects are so expensive, and so way off even to transport brackish water here, the problem is so urgent, we need interim measures to address the Corral de Tierra overdraft problem. I would like staff to provide additional thoughts on my recommendations.	Comment received.	Meeting comment - noted.

301					Meeting	5/7/2021	Janet Brennan	GSA's have the ability to fallow land. If that's not a land use application, I don't know what is. There may be indirect relationships. We can't rezone it ourselves. The county has to understand the seriousness of the problem. If they're approving developments in the B8 Zone, there is obviously a lack of understanding about the groundwater impacts. This is an opportunity to establish a relationship.	Emily Gardner: We can be really thoughtful about our relationship with the county and their process. Staff can explore this, and think through how we address it. Gary Petersen: Land use and SGMA, SGMA can't override land use. Once a SGMA plan is in place, then general plans have to consider SGMA plans. We're at a transition place for that. As land use plans are developed, they have to consider the GSP. We have to investigate further and bring back more information. Sarah Hardgrave: Whether or not the GSP and land use decision making process needs to consider on the land use side. The recent project Beverly mentioned, I provided our information from these efforts to one of our land use planners. This is not an adopted plan, so at this point in time, our efforts are not appropriate to take into consideration. Then in the future, does the GSP become something land use jurisdictions consider in their decision making process? That's the question.	Meeting comment - noted.
302					Meeting	5/7/2021	Janet Brennan	Motion: Request SVBGSA staff to address expanding the B8 area as a program to address groundwater extraction in the Toro Area.	Comment received.	Motion passes.
303					Meeting	5/7/2021	Janet Brennan	I think it would be helpful if staff summarized recommendations like "one more monitoring well". Summarize recommendations so the committee is fully aware of what the draft is recommending.	Comment received.	Meeting comment - noted.
304					Meeting	5/7/2021	Bob Jaques	My general comment for both subareas monitoring well networks is both of those subareas abut the Seaside Subbasin, and we know they're hydrogeologically connected and each subbasin can affect the other. I suggest the monitoring network be expanded to include existing monitoring wells in the Seaside Basin that are close to the border, so the effect of any projects or management actions, can be measured to determine the effect they have on the Seaside subbasin. I will also submit comments online as well.	Abby Ostovar: I need to check to see if we can have wells outside of the subbasin included in the monitoring network. We include wells outside for drawing contours, but I'm not sure if we can have wells outside of the subbasin as representative monitoring sites. Tina Wang: The wells we are talking about here are to meet the requirements. It does not prevent us from collecting date from outside the subbasin. It doesn't prevent us from looking at data from adjacent basins.	Meeting comment - noted.
305					Meeting	5/7/2021	Margaret Anne Coppernall	Do we know how many new wells we need, and how much they will cost? Seawater intrusion is such an important issue.	Abby Ostovar: We haven't looked at the cost yet. We will look at existing wells before we install new wells. Patrick Breen: We haven't worked a cost estimate. It depends on type, depth, levels. Some of that needs to be determined before we provide a cost estimate.	Meeting comment - noted.
306					Meeting	5/7/2021	Margaret Anne Coppernall	How many would you need to install?	Tina Wang: Near the coast would be a great location for nested wells for seawater intrusion and monitoring in the deep. We'll look at this for implementation chapters. We're in the process of identifying how many we need.	Meeting comment - noted.
307					Meeting	5/7/2021	Margaret Anne Coppernall	I'm impressed with this chapter, it's so thorough. You did a great job here.	Comment received.	Meeting comment - noted.
308					Meeting	5/7/2021	Sarah Hardgrave	We're focused here in the Corral area. I will comment on the Marina-Ord side, on the seawater intrusion maps, they have this area with question marks. If we can get to answering those question marks, that would be great.	Patrick Breen: We've had meetings to address those.	Meeting comment - noted.
309					Meeting	5/7/2021	Sarah Hardgrave	The Watermaster was grappling with monitoring well issues on the Fort Ord-9, just on the boundary line. Hoping there can be some good collaboration.	Patrick Breen: We're aware and we agree. We'll work with the watermaster to address those issues.	Meeting comment - noted.
310					Meeting	5/7/2021	Sarah Hardgrave	On the Corral side, are you saying there are potentially existing wells to use first?	Abby Ostovar: We're not aware of any existing data collection in those areas, but if there are wells we can perhaps start collecting data.	Meeting comment - noted.
311					Meeting	5/7/2021	Sarah Hardgrave	It came to my attention that Cal-Am is planning to drill a new well for their Toro system. The well that is no longer functioning is being planned to be turned into a monitoring well.	Comment received.	Meeting comment - noted.
312					Meeting	5/7/2021	James Sang	How will you have projects that will refill each aquifer at one time?	Abby Ostovar: Each of the projects will look at which aquifer they impact. None of the projects promise to refill all aquifer at any one time.	Meeting comment - noted.
313					Meeting	5/7/2021	James Sang	Then you will have some wells that will receive a benefit and some wells will go dry.	Abby Ostovar: There could be varied benefits. We will look at what the conditions are throughout the subbasin and have projects to address conditions in all areas.	Meeting comment - noted.

314					Meeting	8/10/2021	James Sang	I was reading through the paperwork and I noticed there were 10 of 15 areas in the Fort Ord area that were contaminated with fluorocarbons. Should we be concerned about that? Because if we try to do any recharge in this area, they left this contamination behind.	Comment received.	Meeting comment - noted.
315					Meeting	8/10/2021	Sarah Hardgrave	I think that is a good question related to the Marina Ord management area.	Patrick Breen: Yes, it is being considered, and the plans are not going to have an impact on the US Army's effort to clean that up. Tina Wang: It's an important thing to note, most of the remediation effort is conducted in the shallow aquifers, which are the Dune Sands and shallow 180. Most of the groundwater activities are in the lower aquifers. We are coordinating with the Army, we are going to comply with any remediation project restrictions. We have described that in Chapter 3 of the GSP, described in the groundwater restriction areas because of the remediation efforts being done there.	Meeting comment - noted.
316					Meeting	8/10/2021	Sarah Hardgrave	Who are the entities responsible for monitoring the exceedances of drinking water and how that might vary depending on the size of the system?	Abby Ostovar: Drinking water standards? We monitor those to sustainable management criteria. Systems that have over 15 connections, those are monitored by the state. Monterey County Health Department monitors 2 to 14 connections.[Correction: Monterey County monitors systems with 2-199 connections, and the State compiles data for systems 15 and larger].	Meeting comment - noted.
317					Meeting	8/10/2021	Sarah Hardgrave	In Chapter 8 where this is discussed more in depth, are *de minimis* wells, the domestic wells, included in this? Are the wells monitored in the same way?	Abby Ostovar: *de minimis* wells is based on how much you pump. Generally domestic wells aren't monitored for [Title 22] groundwater contaminants, but water systems wells are.	Meeting comment - noted.
318					Meeting	8/10/2021	Sarah Hardgrave	For this particular subbasin, with naturally occurring arsenic, are small systems monitored for that?	Abby Ostovar: The county does, and you can see which ones have exceedances. To my knowledge, there is no government regulated monitoring for domestic wells [with a single connection].	Meeting comment - noted.
319					Meeting	8/10/2021	Sarah Hardgrave	For the sustainable management criteria for water quality potentially being correlated to groundwater levels, if the groundwater levels were to lower with the naturally occurring arsenic, could that potentially increase the amount in the wells?	Abby Ostovar: There are many different factors that could affect that, but it is a potential. We don't have enough data to know if there is a certain depth where you will find more arsenic. We know in this area it is naturally occurring, and depth dependent, but we don't have enough information.	Meeting comment - noted.
320					Meeting	8/10/2021	Janet Brennan	I'm concerned about letting groundwater levels decline in the Corral de Tierra subbasin, I don't think it's a prudent approach given the water quality issues. Furthermore, allowing water levels to decline is going to exacerbate the issues in the Laguna Seca. I do not support the level at which the chapter recommends [2015].	Abby Ostovar: This committee set the minimum thresholds and measurable objectives, it's a prerogative that this committee make a decision on which ones are appropriate for this subbasin.	Meeting comment - noted.
321					Meeting	8/10/2021	Beverly Bean	At the last meeting, Janet made a request that the staff address expanding the B8 area as an action to prevent further groundwater extraction. What is going on with that?	Sarah Hardgrave: It is not currently on the agenda, and I recommend that we discuss it under future agenda items.	Meeting comment - noted.
322					Meeting	8/10/2021	Janet Brennan	I support all the comments LandWatch submitted, and the committee should have a chance to review and respond to those comments. I think the water levels should not be allowed to decline in the Corral de Tierra area.	Comment received	Meeting comment - noted.
323					Meeting	8/10/2021	Beverly Bean	I want some clarity on what was just stated. Will the letters be a part of the public record, and how will that happen? I am not familiar with the letter spreadsheet	Emily Gardner: I will forward it to you now. If someone says please forward this to the committee, we do that. If they don't say that, we add it to our letters, and we post it to our website. This area requires a lot more collaboration with Marina Coast. We can just post what we have to the website.	Meeting comment - noted.
324					Meeting	8/10/2021	Sarah Hardgrave	Is it our responsibility to go look for these letters, or will they be included in future meeting material? Then a 90 public comment period. I'm not sure our committee will have the benefit of weighing in during that time. If we can see anything that comes in, it would be helpful.	Comment received	Meeting comment - noted.
325					Meeting	8/10/2021	Beverly Bean	I see the comment table always comes to us and I think letters should also be included. Letters should be noted and sometimes summarized. At this point, I don't want to miss out on public comments. I think these should be shared with materials and on the website.	Comment received	Meeting comment - noted.
326					Meeting	8/10/2021	Sarah Hardgrave	I also think the letters should be available to the public, which is why they're on the website.	Comment received	Meeting comment - noted.
327					Meeting	8/10/2021	James Sang	The issue of arsenic is really the first time I've heard about this. This is really important because it really increases a person's chances of getting cancer. Can you send out a notice to let people know there is a little more arsenic in their wells?	Comment received	Meeting comment - noted.
328					Meeting	8/10/2021	Sarah Hardgrave	I believe that is the responsibility of the Monterey County Health Department, and residents in this area are generally aware of this.	Comment received	Meeting comment - noted.

329					Meeting	8/10/2021	Sarah Hardgrave	In Section 8.5, there's discussion of the process of input, in that particular section it talks about the agreement between the GSAs and Technical Advisory Committee and the stakeholder committees. It doesn't talk about this committee, and I would ask that that be added. Do our two GSA technical experts feel there is adequate and broad enough coverage? Are there areas where new wells are recommended?	Abby Ostovar: It's in Chapter 7, the Monitor chapter. There are data gaps and we do recommend the installation of new wells there.	Meeting comment - noted.
330					Meeting	8/10/2021	Sarah Hardgrave	There were a whole lot of graphs for wells, I would suggest the bulk graphical information be put into an appendix and it can be quite a bit of pages, and maybe those could go to the back for ease of read. Just a suggestion. Then, I was very interested to see all those tables and graphs because it showed areas where the groundwater levels were in a steeper decline. I was concerned to see that in some of the Deep Aquifer wells. I was concerned to also see the groundwater decline in the MPRWMD Fort Ord wells, which are in that Seaside-Marina-Ord boundary. Which is not our group, but wanted to make that observation. There is a fair amount of discussion in this chapter about coordinating with adjacent subbasins. We don't have Bob Jaques here today, but I hope he will bring this to the Watermaster Board to comment and discuss the hydraulic connection on the Seaside side.	Comment received	Meeting comment - noted.
331					Meeting	8/10/2021	Beverly Bean	I agree with Janet, I think the [GWL SMC] needs revisiting.	Comment received	Meeting comment - noted.
332					Meeting	8/10/2021	Gary Kreeger	I agree as well, at the very least I would like to see the staff come back and address what is in the LandWatch letter.	Comment received	Meeting comment - noted.
333					Meeting	8/10/2021	Sarah Hardgrave	When will the groundwater levels information for this past year be added?	Abby Ostovar: We have groundwater levels information through this spring. To avoid having a lot of iterations, the "current" year is 2019 for the GSP.	Meeting comment - noted.
334					Meeting	8/10/2021	Sarah Hardgrave	Given that we had such a dry year, I'd be interested to see what happened this last year.	Abby Ostovar: If revisiting the groundwater levels, it would be helpful to have more guidance on the information that you would find helpful to make a decision, given that time is really tight.	Meeting comment - noted.
335					Meeting	8/10/2021	Sarah Hardgrave	I think we had considerable information at another meeting, and graphs, and years related to our minimum threshold and measurable objective. I think it would be worthwhile to go through that again, considering the letters received. I think it would be worthwhile for this group to see that again and how it was developed.	Comment received	Meeting comment - noted.
336					Meeting	8/10/2021	Janet Brennan	I think the new information received is the relationship between groundwater level and quality. I think this is important to Corral de Tierra. I know staff has said it is difficult to establish the relationship. There is one. We should take a conservative approach in addressing groundwater levels to assure they do not decline in future years. I'm not sure that setting groundwater levels at the 2015 level accomplishes that.	Comment received	Meeting comment - noted.
337					Meeting	8/10/2021	Sarah Hardgrave	If you all (Abby) could plan to prepare a memo that is more specific to the Corral de Tierra conditions, and lay that information out for us to have a discussion, that would be helpful.	Comment received	Meeting comment - noted.
338					Meeting	8/10/2021	Sarah Hardgrave	This is a lot of really good information, and a lot to digest. I'm hoping this presentation will get posted to our webpage, so there is a little more time to look through it.	Comment received	Meeting comment - noted.
339					Meeting	8/10/2021	Janet Brennan	[Re: Model accounting for rainfall intensity and runoff vs recharge] That is not the information we have received previously, we heard that the DWR model doesn't take into account increased intensity [and that is a major flaw in the climate change scenario].	Comment received	Meeting comment - noted.
340					Meeting	8/10/2021	Janet Brennan	I think staff was going to look at a project that would request the county extend the B8 zoning to the residential users on subdivisions?	Emily Gardner: We are working on that. I did speak to legal counsel about that, and we're working on developing a program where we can coordinate with the county. We're working on it and can bring it to the next meeting.	Meeting comment - noted.
341					Meeting	8/10/2021	James Sang	I feel like in the Corral de Tierra area, I see a great potential for using swales or trenches for capturing rainwater. I think all the water coming out of the hills at the base of the hills, you could collect a lot of water in that area. In the Marina area, a waste treatment plant would be great for the area with more population. Plus an area with a lot of sand, you could put trenches and swales there and capture a lot of water.	Sarah Hardgrave: Thank you, I believe those are captured in the decentralized stormwater and rainwater projects.	Meeting comment - noted.
342					Special Meeting	8/25/2021	Janet Brennan	I have several questions about that chapter [8], about groundwater levels and impact to the Seaside Basin. Especially those issues raised in the Land Watch letter.	Emily Gardner: We have that agendized to discuss it today. Depending on your feedback today, it will be incorporated into the chapter.	Meeting comment - noted.

343					Special Meeting	8/25/2021	Sarah Hardgrave	We'll provide input today and depending on the outcome, if there are changes will you post a revised version of the chapter?	Emily Gardner: We'll email and post it. Again, we can get feedback at the September 8 meeting.	Meeting comment - noted.
344					Special Meeting	8/25/2021	Janet Brennan	Do we recommend approval of the Monterey Subbasin GSP?	Emily Gardner: It has depended on each subbasin committee, how formal/informal they want to be. You can be formal and approve each chapter or you can wait until the whole draft GSP in one piece on September 8, and approve it to send it to the Board. Or just have general consensus.	Meeting comment - noted.
345					Special Meeting	8/25/2021	Sarah Hardgrave	If our committee is not able to reach agreement or take a formal vote, individual committee members can still provide comment during the comment period?	Emily Gardner: Yes. There have been some committees that have said the GSP is okay, but acknowledge that there are still things that need work. It's a living document.	Meeting comment - noted.
346					Special Meeting	8/25/2021	Bob Jaques	If we get 3 chapters, and the entire GSP shortly before the September 8 committee meeting, that will be a lot to review. It will be hard to think you will get a motion to approve.	Emily Gardner: We recognize that. We're hoping you will take us up on the 45-day comment period. We're working on the other deadlines for notification.	Meeting comment - noted.
347					Special Meeting	8/25/2021	Sarah Hardgrave	I would just suggest, to think about, whether there would be a possibility for this committee to get together one last time during that 45 day comment period.	Emily Gardner: Yes, that's what we've been tentatively planning with the other subbasins, to review any substantive changes and get feedback.	Meeting comment - noted.
348					Special Meeting	8/25/2021	Bob Jaques	Interested in if there are any pumping depressions within the subbasin.	Comment received	Meeting comment - noted.
349					Special Meeting	8/25/2021	Sarah Hardgrave	I'll just add that those [Toro and Ambler Park] are both Cal Am systems and Cal Am was at that time adding treatment for arsenic. This is a difference between public systems and small water systems and domestic wells, which don't have treatment.	Comment received	Meeting comment - noted.
350					Special Meeting	8/25/2021	Bob Jaques	I think Option 2 is the best. Adjusting wells individually which would put wells at 2008 levels would be desirable from the Seaside Basin perspective.	Comment received	Meeting comment - noted.
351					Special Meeting	8/25/2021	Janet Brennan	What is the impact of the 2015 minimum threshold on the Seaside Basin? We are already in a trend to exceed the 2015 minimum threshold. You made the argument that if we raise the minimum threshold, we're going to have to implement programs faster than we already have to. What's the difference?	Victoria Hermosilla: My understanding of the modeling data is that there is approximately 400 acre-feet per year water moving from Corral to the Seaside Subbasin. I don't know that we have enough data to definitely say what the impacts to Seaside were. Raising water levels in one area will generally raise groundwater levels in neighboring areas as well.	Meeting comment - noted.
352					Special Meeting	8/25/2021	Janet Brennan	Seems like if you have time for 2015, you have time for 2008. I support Bob's recommendation.	Comment received	Meeting comment - noted.
353					Special Meeting	8/25/2021	Beverly Bean	As a resident of the area, I support 2008 as the way we will get the most aggressive action most quickly. All of this is based on a study that is already old. I favor the fastest approach. Favor Option 2.	Comment received	Meeting comment - noted.
354					Special Meeting	8/25/2021	Patrick Breen	What concerns me is setting these thresholds at a level that we won't be able to meet. Do we have a sense of how many projects this would take to get the water into the aquifer? I don't think hydrogeologically it would impact the Marina Coast Water District Management Area.	DW: There isn't a legal issue with this. It's whether it is practicably achievable.	Meeting comment - noted.
355					Special Meeting	8/25/2021	Gary Kreeger	I understand not doing too big of a lift. We need to think about where we need to be, what the problem we're trying to fix.	Comment received	Meeting comment - noted.
356					Special Meeting	8/25/2021	Janet Brennan	I do not support keeping 2015 levels in the Marina-Ord area because it's allowing seawater intrusion. The coastal well project is pretty much pie in the sky. We have funding issues coming down the line. I think that 2008 is reasonable for the Corral de Tierra.	Sarah Hardgrave: To clarify, you raised the LandWatch letter, and you have similar concerns about the 180/400, correct? Janet Brennan: Correct	Meeting comment - noted.
357					Special Meeting	8/25/2021	Margaret-Anne Coppernoll	On an earlier slide it showed groundwater levels going up in 2017 and then going back down.	Sarah Hardgrave: My layman's response is that in 2015 we were in a drought, and in 2017 we had more rain.	Meeting comment - noted.
358					Special Meeting	8/25/2021	Margaret-Anne Coppernoll	What option gives us the most flexibility to adjust to changes in groundwater levels?	Victoria Hermosilla: You can mix and match and add the management action to any of the other options. Vera Nelson: I just want to clarify that changing the minimum thresholds/measurable objectives in the Corral de Tierra area will not change them in the Marina/Ord area. Changing the minimum thresholds/measurable objectives in the Corral de Tierra will not affect seawater intrusion because the Corral de Tierra is at such a high elevation. In the Marina/Ord area, the plan is to keep the minimum thresholds at 2015 and measurable objectives at 2004/2005.	Meeting comment - noted.
359					Special Meeting	8/25/2021	Beverly Bean	Setting lower elevations would cause us to be in violation of the Sustainable Groundwater Management Act.	Comment received	Meeting comment - noted.
360					Special Meeting	8/25/2021	Bob Jaques	I think it would be good to add the management action in Option 3 to Option 2.	Comment received	Meeting comment - noted.

361					Special Meeting	8/25/2021	Christopher Bunn	I was just curious if the minimum thresholds and measurable objectives for elevations have been contemplated in any expansion plans for the city of Marina.	Abby Ostovar: This discussion is only about the Corral de Tierra area and would not affect the Marina/Ord area. Sarah Hardgrave: Hydrogeologically, where the minimum thresholds and measurable objectives are set in the Corral de Tierra would not affect the Marina/Ord area, but a violation for one management area would be a violation of the Sustainable Groundwater Management Act for the subbasin. Vera Nelson: The projected water budgets and GSP do not address projected increases in groundwater extraction. Sarah Hardgrave: Those are pieces of the plan we'll be looking at during the September 8 meeting. I do look forward to seeing the projected water budget information.	Meeting comment - noted.
362					Special Meeting	8/25/2021	Sarah Hardgrave	I want to bring us back to the water quality/arsenic part of the presentation. If we were to change the minimum thresholds/measurable objectives, it doesn't appear to me that it wouldn't necessarily have an effect on the arsenic. So just to reconnect back to the purposes of this discussion, the overarching questions you're raising Janet are more about water supply and not water quality.	Comment received	Meeting comment - noted.
363					Special Meeting	8/25/2021	Janet Brennan	You're correct, that going to the 2008 level would help the Seaside Basin. I am going to make a motion to change to the 2008 levels and add the management action.	Comment received	Meeting comment - noted.
364					Special Meeting	8/25/2021	Bob Jaques	Our modeling shows that while there is some inflow into Seaside now, if groundwater levels continue to decline, that will reverse and water will flow into the Corral de Tierra. So keeping the minimum thresholds high would not only benefit the Corral de Tierra area, but would be a benefit to the Seaside basin as well.	Abby Ostovar: I just want to make it clear that raising the minimum thresholds/measurable objectives will be a significant lift and would mean pumping reductions or costly supply side projects, and this will mainly have an impact on domestic use in the area.	Meeting comment - noted.
365					Special Meeting	8/25/2021	Ron Stefani	I can't support this motion because of the cost of making this change. It's a heavy enough lift with the current option.	Comment received	Meeting comment - noted.
366					Special Meeting	8/25/2021	Patrick Breen	I'm unclear of the different between Option 1 and Option 2.	Victoria Hermosilla: They are effectively the same, averaged. However, one is that broad brush stroke of adding 5 feet, and the other is pinning the change to the specific year for each well. It averages out to be approximately 5 feet, but some wells are different.	Meeting comment - noted.
367					Special Meeting	8/25/2021	Sarah Hardgrave	I'm going to support the motion, mainly because of the urgency of bringing forward a regional water supply, which would also address the issues in the 180/400. By serving a larger region it would be most cost effective. Our office sees the urgency and for that reason will support motion.	Comment received	Motion passes, 5 yes, 4 no Roll call vote: No - Breen, Coppernoll, Stefani, Storms Yes - rest (5)
368					Special Meeting	8/25/2021	Bob Jaques	I have submitted my written comments yesterday, I want to touch on a few for discussion but the committee. First, many projects and management actions in Draft Chapter 9 don't have cost or estimated unit costs. I'm concerned that without costs, we can't put together a budget, not a water budget, an operational budget. I think you should include that in the chapter. I think we need to do a reality check, some of these projects produce so little benefit, that the unit cost is out of sight. We need to see what is reasonable from a cost benefit standpoint.	Comment received	Meeting comment - noted.
369					Special Meeting	8/25/2021	Janet Brennan	I cannot support this [Regional Municipal Supply Project] unless it is declared that it is publicly owned.	Comment received	Meeting comment - noted.
370					Special Meeting	8/25/2021	Janet Brennan	Recharge to Corral de Tierra from stream channel improvements. How does that water get from stream to Corral de Tierra? I think that should be clarified.	Comment received	Meeting comment - noted.
371					Special Meeting	8/25/2021	Janet Brennan	I think you should clarify water diversion as well. Final point, proposed R2 would generate 15,000 acre-feet of water, and proposal would indicate water would go to agriculture. That's more costly than what agriculture can support. Your analysis needs to indicate if that water is really viable for agriculture.	Comment received	Meeting comment - noted.

372					Special Meeting	8/25/2021	Bob Jaques	There are several places in the chapter, I'm given the impression that pumping reduction may not be necessary. Says 'if pumping reductions are necessary.' I think that should be edited out, because without it, projects and management actions fall short. Also, the discussion about getting reclaimed water, I'm getting concerned that the amount of reclaimed water that can be produced is getting oversubscribed. The 180/400 includes expansion of the CSIP area, so reclaimed water will go there. Seaside Basin also. I think you need to make sure everybody is not making a claim, cause it seems like a lot of folks are looking to that reclaimed water.	Abby Ostovar: We can clarify that in the text. In the plans are the potential projects and management actions. It doesn't mean they will be implemented. For example, the Eastside GSP has two 11043 projects, they're just options. When we get to implementation, we'll decide. I hear your concern about overbanking on M1W.	Meeting comment - noted.
373					Special Meeting	8/25/2021	Bob Jaques	On page 9-1-3, de minimis pumpers, I think it would be worth having some legal review made whether it would be possible for MCWRA to have de minimis extractors file extraction reports. SGMA can't impose a fee on them. Probably a simple legal question, I don't think it would be too hard. I think MCWRA could impose that if it would help with basin management.	Sarah Hardgrave: It's a good question, and I think [legal] council here can consider it.	Meeting comment - noted.
374					Special Meeting	8/25/2021	Beverly Bean	In my opinion, pumping reductions are the only project that will help the groundwater.	Comment received	Meeting comment - noted.
375					Special Meeting	8/25/2021	Patrick Breen	Is there a way to determine what existing pumping would need to be minimized to raise water levels? Would a zero pumping scenario get us there within 20 years?	Abby Ostovar: We can look at it. I would need to talk with our modelers. I'm not quite sure what the capabilities are there.	Meeting comment - noted.
376					Special Meeting	8/25/2021	Patrick Breen	This group needs to understand existing pumping. I'm wondering if we're even in a feasible situation. With raised levels, I'm not sure we can even achieve that.	Comment received	Meeting comment - noted.
377					Special Meeting	8/25/2021	Bob Jaques	If you look at the regional projects, you have substantial amounts, not that it's inexpensive. I think it's achievable, on a regional basis. You look at the unit cost with smaller projects, and they're unachievable. Regional projects, even though capital cost is greater, is more reasonable.	Comment received	Meeting comment - noted.
378					Special Meeting	8/25/2021	Sarah Hardgrave	I agree with you Bob. Many of the Corral de Tierra projects seem like a heavy lift and a relatively small benefit for the effort required. It reinforces my perspective that regional projects are preferable.	Comment received	Meeting comment - noted.
379					Special Meeting	8/25/2021	Gary Kreeger	I want to point out that there will be a heavy cost if we don't turn this problem around. Keep it balanced. Yes there's a cost, but also a cost if we run out of water.	Comment received	Meeting comment - noted.
380					Special Meeting	8/25/2021	John Bramers	It seems like this small Corral de Tierra area will be burdened to pay for these projects, is this area even able to pay? Will Seaside participate, because they will benefit? If the GSP for the Corral de Tierra doesn't go through with the board, is the entire subbasin out of compliance?	Comment received	Meeting comment - noted.
381					Special Meeting	8/25/2021	Christopher Bunn	I very much agree with the comments from Bob and Sarah. I think that's the only way this area can be secured. I think there will be a lot of support from the farming community to the north for the right project. These piecemeal projects, I don't see it happening. The Winter release with ASR is primarily a 180/400 project, that project is something that the farmers won't get behind. If you're going to spend that much capital, you might as well get a proper regional project.	Comment received	Meeting comment - noted.
382					Special Meeting	8/25/2021	Margaret-Anne Coppernoll	I support this [Land Use Jurisdiction Coordination Program] for all the committees to see and understand. I think it's important, this collaboration idea.	Comment received	Meeting comment - noted.
383					Special Meeting		Sarah Hardgrave	I appreciate the inclusion of this language. There have been times when water use has been used as the rationale for land use restrictions, but they are related. My sense is that the concern we've heard from Janet was on the land use jurisdictional side. I think it will take commitment from the jurisdictions to consider the GSPs with their land use decisions. It's not a mandate, and may take more general consensus with respect to GSPs and future updates. It seems like a good generalized statement you've made here.	Comment received	Meeting comment - noted.
384					Special Meeting	8/25/2021	Margaret-Anne Coppernoll	I'll make a motion that we include it in all the GSPs.	Comment received	Meeting comment - noted.
385					Special Meeting	8/25/2021	Janet Brennan	I second.	Sarah Hardgrave: So the motion is to include it [Land Use Jurisdiction Coordination Program] in our GSP and encourage the other subbasins to incorporate it.	MOTION PASSES

386					Special Meeting	8/25/2021	John Bramers	Now that the other GSPS have gone to the Board, would this need to go back to the Board?	Emily Gardner: We did mention this at the Board meeting, that there would be edits to the draft GSPs. There is a version that went out for public comment. But there is a version that will have the edits and go back to the board on December 9.	Meeting comment - noted.
387					Email	9/8/2021	Margaret-Anne Coppernoll	1. Page 10-5 - Footnote, line 2 RWS - should this be RMS? 2. Page 10-7 - last paragraph. the wording seems unclear "and subject to seawater intrusion" - is groundwater elevation monitoring subject to seawater intrusion? I recommend clarification on this sentence. I apologize if I missed the correct connection. 3. Page 10-15 - Section 10.7, 2nd paragraph, 1st word: "Cost" should be "Costs herein are"? 4. Page 10-19: Section 10.7.2.2, line 7- there seems to be an extra word: the costs comprise of (extra word) annual analysis and reporting of sustainability conditions. 5. Page 10-20 - line 4: "permitting associated will (should be "with") all potential projects...." Question: Is it possible to describe or list what the actions are that will be implemented for the $35,000 budget item for supporting deep well monitoring/2022/23? I ask because the other budget items contain a description. Maybe a description is not necessary - just inquiring.	Comment received	Thank you for the edits and suggestions. Revisions in the text have been made.
388					Meeting	9/8/2021	Sarah Hardgrave	Can this committee reconvene during the 90 days? We have to acknowledge it was an 834-page packet that we got on a holiday weekend, and it would have been impossible for all of us to digest the new material and plan as a whole. I would recommend that we have another meeting.	Comment received.	Meeting comment - noted.
389					Meeting	9/8/2021	Margaret-Anne Coppernoll	I like that idea. I think we need some more time.	Comment received.	Meeting comment - noted.
390					Meeting	9/8/2021	Bob Jaques	Would we be able to get a look at what the edits will be so we have something to respond to?	Sarah Hardgrave: I think we can request an update along those lines as part of the agenda materials. So we can leave it flexible for our consultants and GSA staffs for making changes. Emily Gardner: Your next regularly scheduled meeting will be that first Friday in November.	Meeting comment - noted.
391					Meeting	9/8/2021	Sarah Hardgrave	I think that will help today's meeting as well. We know we'll have an opportunity to come back with comments and questions. If you have the opportunity or time, I would encourage you to submit comments online in addition to what you've shared at the meetings.	Emily Gardner: To clarify, there is a 90-day notification to the city and county, the exact comment period will be determined when it is released by Marina Coast Water District. Ours is a little longer than 45 days.	Meeting comment - noted.
392					Meeting	9/8/2021	Sarah Hardgrave	When is the deadline to submit to DWR?	Emily Gardner: End of January, and then there will be another comment period.	Meeting comment - noted.
393					Meeting	9/8/2021	Sarah Hardgrave	To receive this, you are also looking for approval?	Emily Gardner: In general, this committee tends to prefer more formal motions. We just like to take it to the board having been reviewed by the committee.	Meeting comment - noted.
394					Meeting	9/8/2021	Bob Jaques	In the bottom right corner, the Corral water budget zone, net annual change in storage, I know in some of the other slides, I thought the overdraft was 1,000 AFY.	Abby Ostovar: So that was prior to having the model, and that was developed by taking groundwater levels between two different years and using a storage coefficient. The storage SMC here is the difference between the MO/MT.	Meeting comment - noted.
395					Meeting	9/8/2021	Sarah Hardgrave	What is the difference between the sustainable yield and the 1,000 AFY Bob is referring to?		Meeting comment - noted.

396					Meeting	9/8/2021	Bob Jaques	Would the modelers consider the 2,800 AFY to be more reliable than the previous 1,000 AFY?	DW: In a way, Bob, I would say it is more reliable because it is based on a more complete analysis of the basin. I would not say we're going to throw out the 1,000. We will keep it to look at the uncertainties. Yes, it is more reliable, but it is not the final word. Abby Ostovar: Keep in mind, the water budget is a requirement from DWR. It is one aspect to guide management. What we should be focused on is avoiding those undesirable results. Even though we do have imperfect and incomplete information, we know groundwater levels have been declining and that information can help guide management.	Meeting comment - noted.
397					Meeting	9/8/2021	Bob Jaques	What is the timeframe on this?	Abby Ostovar: This is projected out 50 years. Tina Wang: Those should be dates instead of numbers. The reason we're running these scenarios is because this subbasin is very interconnected to the other subbasins. We want to see how the boundary conditions and climate will affect the outcome of the model. The message that we're getting from this analysis is that it's very much dependent on boundary conditions as well as climate.	Meeting comment - noted.
398					Meeting	9/8/2021	Janet Brennan	All of this is going to the advisory committee, and I want to know if the threshold will be revised to the 2008 level before it goes to the advisory committee for consideration. This was one item that has a close vote, and the advisory committee may want to weigh in on this important issue. They should get chapters that reflect our agreement	Emily Gardner: What you're getting today and the board will get tomorrow is a verbal explanation that this has been changed. The plan was to have the advisory committee receive the same draft you received. There are time constraints. If something is ready before, then yes, but hopefully this explanation as Abby has presented is fine.	Meeting comment - noted.
399					Meeting	9/8/2021	Sarah Hardgrave	When we come back to a meeting in late October, hopefully that will be enough time to make those changes. Maybe, to Janet's point, there can be a slide explaining the discussion this committee had on Aug 25 so it's really clear that it happened, and they are receiving the information about it. I think it will continue to be a point of discussion. To Patrick's concern, better understanding of how the revised MT/MO, are we already at the Undesirable Result with the 20% below, and what does that really mean for us? I think there needs to be more discussion on how realistic it would be, especially based on water budget information.	Abby Ostovar: That is what the model shows.	Meeting comment - noted.
400					Meeting	9/8/2021	Sarah Hardgrave	I think we really need to talk about the project options and how far they would get us.	Abby Ostovar: If I get through the rest of the slides, it will get to the projects and we can continue this discussion.	Meeting comment - noted.
401					Meeting	9/8/2021	Bob Jaques	At the last meeting, one of my comments was about *de minimis* wells and requiring them to do reporting. Do you know if any legal look has been made into that?	Sarah Hardgrave: Can we pause on that question, Bob? The supervisors are in a meeting and Les Girard is there. If he can come to this meeting, we can ask him when he joins us here.	Meeting comment - noted.
402					Meeting	9/8/2021	Janet Brennan	Regarding: "There is no known impact to depth and concentrations of arsenic". I think it is more accurate to say there is a lack of data regarding the concentration and depth. Maybe that's a little technical, but it implies that there is no relationship when in fact there is no data to support a relationship. Am I off base? I suggest you change the wording.	Abby Ostovar: I can change that for the board meeting.	Meeting comment - noted.
403					Meeting	9/8/2021	Janet Brennan	I question whether agriculture is willing to pay a municipal cost for that excess water. You may want to note that somewhere.	Abby Ostovar: Part of the reason we have a range here is because it will require a number of conversations about where the water goes. There are a number of steps to bring this to fruition, or really to understand how this should be scoped.	Meeting comment - noted.
404					Meeting	9/8/2021	Margaret-Anne Coppernoll	My concern is related to Bob's question about *de minimis* wells, because that seems to give us a large data gap that is important to close. For the well registration, do we know how many exist? It's important to know considering the drops in the groundwater levels.	Sarah Hardgrave: I believe there is detailed information about the breakout of the different types of systems.	Meeting comment - noted.
405					Meeting	9/8/2021	Margaret-Anne Coppernoll	My question is about the legality and obtaining meters. I liked what Bob had to say and his questions.	Sarah Hardgrave: Again, we're going to hold off on that until legal counsel can join us.	Meeting comment - noted.
406					Meeting	9/8/2021	Steve McIntyre	I think it would be interesting to see when that analysis is done, to look at the reduction in pumping with respect to both the previous SMC and revised SMC, to look at what the difference might be.	Comment received.	Meeting comment - noted.

407					Meeting	9/8/2021	Christopher Bunn	It seems like the more I hear and read through this GSP, the more questions I have. No subbasin is mired entirely in itself, even if the 180/400 farmers meets its MOs, but Corral de Tierra is still losing water, how does the "do no harm" play into that relationship? Will the [Reservation Road areas] be included? Regarding the Regional water supply project and farmers, at municipal [water] cost levels, you can't farm. But I think there could be some kind of window or agreement for farmers to subsidize the cost of that water.	Abby Ostovar: With regards to projects and management actions along the Reservation Road area, we would address this as we go. That is Salinas Valley Basin GSA's responsibility, but any projects and management actions would have to be evaluated on its impact and participation level.	Meeting comment - noted.
408					Meeting	9/8/2021	John Bramers	I heard "need more data" a half dozen times, but we're setting MTs with a lack of data. My question is, we have to be sustainable in 20 years. By putting that MT at 2008, how many pumping allocations and projects will we have to do, and can we even get to that MT?	Abby Ostovar: We don't know at this point what the level of effort will be. It will be substantial regardless.	Meeting comment - noted.
409					Meeting	9/8/2021	John Bramers	How many wells are we looking at right now? If they all fall below, what is that?	Abby Ostovar: We don't know right now.	Meeting comment - noted.
410					Meeting	9/8/2021	James Sang	I notice a lot of wells are located in the southern part of the Corral de Tierra area. You've mentioned several projects, but are they really relevant to raising the water levels in the wells? Will it actually help us raise the groundwater levels in those wells in the southern part of the basin?	Sarah Hardgrave: Thank you for that comment, it reinforces further discussion here.	Meeting comment - noted.
411					Meeting	9/8/2021	Christopher Bunn	If the 180/400 meets the MOs, but Corral de Tierra is still losing water, how does the "do no harm" policy apply?	DW: Part of this is going to be a legal assessment. I would say that the idea is that you cannot prevent a neighboring subbasin from achieving sustainability. What that means has not been tested yet. Does that mean a neighboring subbasin has to have SMC you agree with? We are trying to set up SMC between our GSPs so there won't be a significant gap. It's an advantage to how we're approaching this whole valley. But the answer is it hasn't been tested yet.	Meeting comment - noted.
412					Meeting	9/8/2021	Patrick Breen	Of the 1,200 AFY being pumped, do we know how much is *de minimis* ? Just remind me, does the Sustainable Groundwater Management Act have jurisdiction over overlying pumpers?	Sarah Hardgrave: The first part of your question, one of the reports we received, had a table of the number of water systems and the number of *de minimis* wells, in addition to the small and regulated system. I know that information is available, but not quickly. Abby Ostovar: This was a memo we had the Wallace Group put together on extraction data in the area.	Meeting comment - noted.
413					Meeting	9/8/2021	Patrick Breen	Are we even able to regulate them? Is our ability to regulate them, shouldn't that be considered and weighed?	Sarah Hardgrave: Again, that is a legal question to give to Les. I hope you're keeping a list for him. Emily Gardner: I did ping Les quickly. MCWRA does have the authority to require meters for *de minimis* users, not the GSA. So it would have to be in partnership with them.	Meeting comment - noted.
414					Meeting	9/8/2021	John Bramers	If we can't get *de minimis* users to participate, I don't think we can balance this basin. Even if you can put a meter on those *de minimis* users, can you put an allocation on them? Also, when you talk about a well in the Upper Corral area, where is that going to?	Emily Gardner: I also have the pie chart that shows the percentage of *de minimis* users I can share.	Meeting comment - noted.
415					Meeting	9/8/2021	Janet Brennan	Even if you could regulate all the pumping and reduce pumping by 1,200 AFY, you're still not going to address the overdraft problem. It's more complex than just putting limits or having an allocation system.	Comment received.	Meeting comment - noted.
416					Meeting	9/8/2021	Sarah Hardgrave	If we set the targets at these different levels, we need more information than we have now, and explain what we would need at each level, and how the projects could meet the criteria. I think that goes to James Sang's comment, how we raise the levels. I do continue to see that if the regulated utility system, that would be the most reasonable to tie in to potable domestic water supply, that's the best way to reduce the amount of pumping.	Comment received.	Meeting comment - noted.
417					Meeting	9/8/2021	Patrick Breen	We're showing our water levels generally stabilizing but what we're going to encounter is some current wells going dry. Are we going to spend so much money to avoid a certain amount of wells going dry, or submit a plan where some wells will go dry. I understand the ramifications. In the context of what we're dealing with here, how much money are we willing to spend on a sustainable level, and maybe a sustainable level that is lower than we prefer. How much storage is in the Corral de Tierra area? Do we know that?	Abby Ostovar: We haven't put a number on the storage for the Corral de Tierra. There's a question of if it's feasible. I'm hearing that a lot of this is about trade-offs. Patrick, you put it well. Domestic wells were prioritized here, but the trade-off is cost. That conversation about projects and management actions to implement, and which will be prioritized, is where we'll head for implementation.	Meeting comment - noted.

418					Meeting	9/8/2021	Bob Jaques	In one of the earlier chapters there was a graph showing groundwater levels over time. And the groundwater levels continue to decline for a number of years and then they go up after projects and management actions are implemented. I'm curious how the rebound is determined. From the current list of projects and management actions, it doesn't look like we'll get there. Even if you turn off all the pumping, you're saying here that we won't get there. So it seems like someone was making assumptions about when those projects and management actions will be implemented. Do you recall that slide? Is that something that can be easily explained?	Abby Ostovar: I think what you're thinking about is the Marina-Ord area. We don't have "a project" scenario. Are you referring to interim milestones? It is just showing what will be needed to reach those levels.	Meeting comment - noted.
419					Meeting	9/8/2021	Bob Jaques	If those are interim milestones, if there was a way that those have been determined.	Abby Ostovar: It's not tied to specific projects. It assumed it will take a few years to implement and it will take some time to rebound.	Meeting comment - noted.
420					Meeting	9/8/2021	Bob Jaques	Okay, you may want to highlight that a little more because I didn't pick that up.	Comment received.	Meeting comment - noted.
421					Meeting	9/8/2021	Sarah Hardgrave	I think in this time, we've made some suggestions on what type of additional discussion is needed and time to review the documents and develop more comments and questions. I think at this time, our committee should recommend releasing this document for review.	Comment received.	Meeting comment - noted.
422					Meeting	9/8/2021	Patrick Breen	I make a motion	Comment received.	Motion passes, draft released for review
423					Meeting	9/8/2021	Margaret-Anne Coppernoll	I second it.	Comment received.	Meeting comment - noted.
424					Meeting	9/8/2021	Sarah Hardgrave	Bob and I did give an overview presentation to this to the Seaside watermaster. I will add one comment on the plan. In Chapter 2, there wasn't much mentioned on the need for coordination with the adjudicated basin. I noticed that was a missing piece. The shared boundary between Marina Coast and the FO-9/10 wells have been a subject of discussion of the watermaster.	Comment received.	Meeting comment - noted.
425					Meeting	10/22/2021	Bob Jaques	Are there comments from the online form? I see there are always different spots. I really like to look at the next versions of the draft GSP, because so many comments are made and it's nice to see where revisions are made from comments.	Emily Gardner: Yes, we are working on it as fast as we can. We will try to get it at the end of November. We're going to try to get it to you as soon as possible.	Meeting comment - noted.
426					Meeting	10/22/2021	Sarah Hardgrave	There have been quite a few comment letters that are comments on multiple subbasins. It's a little bit of a task to comb through and see what is specific to the Monterey Subbasins. Is MCWD receiving separate comments? Are they preparing separate responses?	Patrick Breen: It's my understanding that EKI and Montgomery are compiling the responses together into one table.	Meeting comment - noted.
427					Meeting	10/22/2021	Janet Brennan	Re: Undesirable Results. This section about GSA projects to not let water levels fall below minimum thresholds, that suggests to me there is a relationship between groundwater levels and quality. Previously, the conclusion was that they could not establish a relationship, this implies there is a relationship, this seems to be a change in direction.	Abby Ostovar: You're correct. When we looked at arsenic, we couldn't find a relationship with groundwater levels. This is a more general statement that deals with all constituents of concern. It's one of the strategies we will use to make sure we don't have degradation, but we would have to look at each constituent individually. Emily Gardner: Exceedance of minimum thresholds refers to water quality specifically.	Meeting comment - noted.
428					Meeting	10/22/2021	Sarah Hardgrave	I have the same observation as Janet, so thank you for the clarification. I am hearing what you're saying about arsenic and the relationship with groundwater levels in the Corral de Tierra. It's a very specific constituent of concern. There isn't a clear relationship between groundwater levels and naturally occurring arsenic. For other constituents, groundwater levels can impact quality. This statement will be applied to all constituents in all subbasins. I'm just restating what you said so I understand.	Comment received.	Meeting comment - noted.
429					Meeting	10/22/2021	Sarah Hardgrave	I'm wondering if in the Monterey plan, if the clarification we made here can be added for the Corral de Tierra area. Specific concerns about arsenic and groundwater levels can be clarified, not necessarily influenced by groundwater levels. The challenge we have is that it's naturally occurring and not related to the overpumping issues we have. I would also assume that over time, there will be careful monitoring to see if there is a greater relationship than is currently understood.	Emily Gardner: In our definition of undesirable results, or the SMC chapter, perhaps where we talk about general groundwater quality. Abby Ostovar: We could reference it where we do talk about it. If someone just reads this, they might miss it. Emily Gardner: Yes we can point back to how we describe it elsewhere in the GSP.	Meeting comment - noted and incorporated

430					Meeting	10/22/2021	Bob Jaques	Re: model results: I think more than anything, this shows how severely in overdraft this subbasin really is. Regardless of the minimum thresholds/measurable objectives, if you stop all pumping, you just have an unsustainable condition.	Comment received.	Meeting comment - noted.
431					Meeting	10/22/2021	Janet Brennan	I was going to make a similar observation. No matter what we adopt. Even if we stop all pumping, we continue to decline because of leakage to other subbasins?	Abby Ostovar: Yes.	Meeting comment - noted.
432					Meeting	10/22/2021	Steve McIntyre	So if there is leakage, and you stop all pumping, is there also the possibility that adjoining subbasins is somewhat harming this subbasin? Hydrologically, I'm sure there is another term for it.	Abby Ostovar: It is interconnected with other subbasins. Part of this is a challenge because we are projecting other subbasins' groundwater levels which we don't really know. Any model is also built on the best available data, and there are uncertainties including several data gaps in this area. This area is largely not covered by GEMS. The estimation of extraction may be less than what is actually occurring. But yes, this is related to adjacent subbasins, in as much as other adjacent subbasins are impacted by Corral de Tierra.	Meeting comment - noted.
433					Meeting	10/22/2021	John Tilly	Are you aware of how much is going into the Seaside Basin too?	Abby Ostovar: I would need to look at the relationship again. We've talked to the watermaster as well. That area has a three-way partial groundwater level flow divide. We have some information about it, but it's tricky to understand what is going on there. Even with the modeling, it's a tricky area to understand.	Meeting comment - noted.
434					Meeting	10/22/2021	Bob Jaques	One of the difficulties is that the modeling the watermaster has done in the past, we modeled the Paso Robles Formation and Santa Margarita Formation as separate aquifers. The Monterey model has modeled them together as a single aquifer, the El Toro. Their modeling shows an inflow to the Laguna Seca, and our model shows an outflow from the Laguna Seca. We expect in the early years of implementation we will find compatibility between the two approaches. The two aquifers, grouped together, are grouped from a lack of additional monitoring input. They will need to be separated to view the outflows and inflows.	Abby Ostovar: We did talk about this to figure out what the discrepancies are, and they have different boundaries and different future assumptions. We started to look at how those simulations work differently. In the EKI model, they do separate out the formations, but for the GSP they are grouped.	Meeting comment - noted.
435					Meeting	10/22/2021	Beverly Bean	It seems to me that this kind of slide should be in the report and used as a wake up call to the powers that be, the political powers. For people to understand that this aquifer is so severely impacted, I want to know if you will put a no pumping scenario in the plan. I hope it wasn't brought back to us to revise the SMC.	Abby Ostovar: One idea we had for this committee, we were thinking this could be brought into the report as a project scenario like MCWD has, and perhaps into Chapter 9.	The no pumping scenario output was added to the plan
436					Meeting	10/22/2021	Janet Brennan	I'm inclined to go back to the original SMC, to keep it in the realm of possibility. Our recommendation will impact the general population, it impacts all the residents in the Corral de Tierra. We have limited participation from that community. I'm really concerned about adopting something that is beyond any reasonable expectation.	Comment received.	Meeting comment - noted.
437					Meeting	10/22/2021	Bob Jaques	Our concern is that our modeling indicated we will lose water even if we stop all pumping. If we do, the water rises and the gradient slopes more steeply to the Corral de Tierra. So then we're unsustainable, but how much more can we do beyond not pumping? We're already looking at other water for our subbasin for replenishment. As we talked at the last meeting, if we can generate new water, it sounds like all subbasins are in need of a new water source. I follow the 180/400, and they have their extraction barrier and potential desalination. We see the Corral de Tierra and Monterey Subbasin leaks a substantial amount of water to the 180/400. If the 180/400 could stabilize, it seems like it would solve some of the Monterey issues. We're just concerned about the Corral de Tierra area water levels not being brought back up.	Comment received.	Meeting comment - noted.
438					Meeting	10/22/2021	Sarah Hardgrave	The Seaside Basin has already gone through their step-wise reductions, and we're still having issues.	Comment received.	Meeting comment - noted.
439					Meeting	10/22/2021	Janet Brennan	The failure of all these sub-plans is to not identify a regional solution for the Salinas Basin that address the need for redistribution of water within the entire basin. That is a major concern of all of us. We just need to have a more comprehensive view and regional approach than just looking at projects. Some southern subbasins are not looking at the redistribution of water and we need to have a coordinated approach.	Comment received.	Meeting comment - noted.

440					Meeting	10/22/2021	Beverly Bean	While I certainly agree with the regional needs, I want to take up the comment on the participation of Corral de Tierra residents. They pump happily away without realizing they are contributing to a problem. I think the "no-pumping" slide should be in the plan, and I don't think we should change the SMC back to the original levels. I think this needs to be a dramatic warning.	Comment received.	Meeting comment - noted.
441					Meeting	10/22/2021	Ron Stefani	I am going to support the original SMC. Staff didn't pick that number out of the air. There has been a lot of work that has gone into this. If we can meet the minimum threshold and measurable objectives, they can be moved again later down the road.	Comment received.	Meeting comment - noted.
442					Meeting	10/22/2021	Steve McIntyre	I have to agree with Beverly, that 95% of the Corral de Tierra residents don't have a clue, and I'm one of the 95%. As much as I am involved elsewhere. I think the slide today is quite dramatic, and we should include it in the GSP. I think this needs critical attention, and we won't get it without some shock value.	Comment received.	The no pumping scenario output was added to the plan
443					Meeting	10/22/2021	John Bramers	I don't disagree with putting it in the GSP, and I do agree with putting it back to 2015. Did we ever get clarification that *de minimis* users, and how they will participate in restrictions? I remember that was key. We still need to get that clarification. Are we going to have leakage no matter what? Is leakage a pat of not being able to get to sustainability? Do we have to get to a point where there's no leakage?	Abby Ostovar: The Salinas Valley is hydraulically connected. You will never operate in a vacuum. This area is the area of recharge for here and the areas around it. We won't get no leakage, we all have to work together to get to our undesirable results. They are connected, and it's a joint effort no matter what. Emily Gardner: The authority around regulating *de minimis* users. While the GSA has limitations on how the regulate *de minimis* pumpers, the MCWRA does have that authority. So we'd have to work through the MCWRA. Donna Meyers: The County of Monterey also has that ability as well.	Meeting comment - noted.
444					Meeting	10/22/2021	Sarah Hardgrave	I'll make a motion to go back to the 2008, 2015 SMC levels that had been in place prior to the August meeting.	Motion Passes	SMC for groundwater levels was adjusted based on Subbasin Committee vote
445					Meeting	10/22/2021	Janet Brennan	I'll send this comment on to staff so you can understand it. This whole section needs clarification, it's based on so many assumptions. 'Sustainable' is based on other basins meeting their obligations. If you could re-take a look at that page and make it understandable for the lay person, I would appreciate it.	Donna Meyers: We're happy to do that, no problem.	Meeting comment - noted.
446					Meeting	10/22/2021	Margaret-Anne Coppernall	I just want to bring up the *de minimis* wells again. I wonder how many there are and how much they're pumping. There's no way to know how much they're pumping. We need to include them in the equation because it is going to affect everybody. We need the information to make the correct decisions. It will require everybody. Do we know many *de minimis* wells there are?	Abby Ostovar: We did an analysis on parcels, assuming if they weren't served by a water system, they would be on a well. We applied an average household use, and other reasonable assumptions. We don't know exactly because there hasn't been measurement in this area.	Meeting comment - noted.
447					Meeting	10/22/2021	Sarah Hardgrave	It was something like 150 or 160 wells?	Abby Ostovar: Just to clarify, one definition is 'individual households' and another is 'less than 2 acre-feet per year'. The estimation of *de minimis* use here is based on individual parcels. Some small water systems would be considered *de minimis* because they might use less than 2 acre-feet per year, but they are included under mutual water systems.	Meeting comment - noted.

448					Meeting	10/22/2021	Bob Jaques	I just, earlier this morning, got a chance to read through the LandWatch letter, it was quite a lengthy letter. One of the things they go through strongly is the issue of financial ability to do projects. It seems to be a comment regarding listing projects, and not adequately demonstrating the financial ability for the GSA to carry the scenario out. It's striking for the Corral de Tierra area, and the ability to bring in new water sources, and the incredibly high cost to go along with that. I was disappointed to see the graphic on the 50-year period. I asked Abby how water levels would rebound during implementation, and the response was that it was assumed that projects would be implemented to achieve that. Part of the comment letter from LandWatch was that it was insufficient. Every project, when you add them all up, it's not enough. It's going to be hard for DWR to approve this. Even if we go back to other groundwater levels, the rationale is not supported with facts. That is something that should be addressed here for an acceptable GSP. I wanted to put that here as a comment. After reading that, I share their concerns.	Abby Ostovar: You did hire M&A to write a passing plan. This takes a similar approach as the 180/400, and this plan is more reasonable. We do believe this is a passing plan for DWR. It doesn't mean it won't be a heavy lift. DWR doesn't need to know exactly what you will do and how you will finance it. They want to know you have a range of options that you will develop funding mechanisms as you go. I think everyone here knows you will need to move quickly in this area.	Meeting comment - noted.
449					Meeting	10/22/2021	Janet Brennan	There is a difference between which deciding which projects and having an overall view of the viability of any project. Given the lack of regional consensus, many of the projects that will address the problem are not viable. There is a step between just listing a bunch of projects and having more information, we could have more information on some of the projects on the viability of the solution. That is what LandWatch is looking for.	Sarah Hardgrave: I just want to say again, we're planning to hold a community meeting on Nov 17 for the Corral de Tierra, and our outreach for that meeting will hopefully include several advertisements through several channels. We will ask staff to provide feedback at this meeting. We are tentatively looking to hold it in person, perhaps at San Benancio Middle School. Related to this discussion, supervisor Adams made a board referral on regional projects identified in the GSPs. This conversation emphasizes the importance of meeting with these stakeholders. There is not any desire or intent to step on the toes of the GSA or MCWRA, just a recognition that the board of supervisors are not fully familiar with what is coming out of the GSPs. Just want to have a common understanding of the GSPs, and a better understanding of these regional concepts. We have been talking with staff to do this in early December. It's not a referral to alter or change the GSPs, more to figure out next steps. Recognizing the GSA has plans for the integration, so multiple agencies and community leaders can have a more common understanding, and not just the folks who have been more active.	Meeting comment - noted.
450					Meeting	10/22/2021	Sarah Hardgrave	We're planning to hold a community meeting on Nov 17 for the Corral de Tierra, and our outreach for that meeting will hopefully include several advertisements through several channels. We will ask staff to provide feedback at this meeting. Related to this discussion, supervisor Adams made a board referral on regional projects identified in the GSPs. This conversation emphasizes the importance of meeting with these stakeholders. There is not any desire or intent to step on the toes of the GSA or MCWRA, just a recognition that the board of supervisors are not fully familiar with what is coming out of the GSPs. Just want to have a common understanding of the GSPs, and a better understanding of these regional concepts. We have been talking with staff to do this in early December. It's not a referral to alter or change the GSPs, more to figure out next steps. Recognizing the GSA has plans for the integration, so multiple agencies and community leaders can have a more common understanding, and not just the folks who have been more active.		Meeting comment - noted.
451					Meeting	10/22/2021	Bob Jaques	Would you be able to have that November 17 meeting to have a public display, like in the newspaper? Some folks may not otherwise be informed.	Emily Gardner: We have published previous notifications in the Monterey County Weekly.	Meeting comment - noted.
452						12/13/2021	**Janet Brennan**	Our agenda says to receive the Monterey Subbasin Plan, and that means we can recommend an action on that plan. I find that wording to be misleading. I would encourage staff to indicate that an action item is being contemplated. That is my comment on how the agenda is worded. Second, MCWD GSA, do they submit the whole plan included the part of the CDT area? Or just their part?	**Emily Gardner:** Just one plan, they submit the whole plan.	Meeting comment - noted.

453					Meeting	12/13/2021	**Sarah Hardgrave**	That submittal by MCWD is pursuant to the agreement between the GSAs?	**Emily Gardner:** We're following the spirit of the agreement. They will submit in January. **Patrick Breen:** It's a similar practice we follow with the 180/400. As the SVBGSA was the lead on that plan, they submitted. Since MCWD is the lead on this plan, we will submit based on the framework agreement even through there are different management areas.	Meeting comment - noted.
454					Meeting	12/13/2021	**Norm Groot**	Building on committee member Brennan's comment, if there are revisions suggested, and also at the Advisory Committee meeting, is there a possibility there will be another special meeting to review those changes, and in effect, approve them? I'm just wondering if there will be substantive changes made.	**Comment received**	Meeting comment - noted.
455					Meeting	12/13/2021	**Sarah Hardgrave**	I think if there are substantive changes this committee would want to review them.	**Emily Gardner:** If there are, we could reconvene. But we are getting up to the deadline here. There is another meeting on the schedule just in case. Since there are two GSAs, it takes more coordination. If there are suggestions today, it would be great to land on the language you would like to see, and that would go to the board. I would like to make best use of our limited time.	Meeting comment - noted.
456					Meeting	12/13/2021	**Sarah Hardgrave**	Give that the purview of this committee is on the Corral de Tierra area, I would like to focus on that. If there are significant changes for the Marina-Ord area, I would not recommend we meet again to review those changes. I'm posing this as a question.	**Comment received**	Meeting comment - noted.
457					Meeting	12/13/2021	**Janet Brennan**	Are you saying we shouldn't be commenting on the entire plan? I have comments on the Marina portion, so what are you saying?	**Comment received**	Meeting comment - noted.
458					Meeting	12/13/2021	**Sarah Hardgrave**	Yes we should comment on the plan as a whole, but I would suggest comments on the Marina-Ord area should be given to the MCWD GSA board. I would recommend that.	**Donna Meyers:** Any members of the committee should submit your comments on that part of the GSP to the MCWD GSA board as well. Our two agencies have a cooperative agreement where MCWD GSA is the lead on the GSP. It's helpful for them to get those as wells.	Meeting comment - noted.
459					Meeting	12/13/2021	**Janet Brennan**	Based on what Patrick said earlier, they are prepared to address some changes we recommend. We are being asked to forward and recommend approval of this entire plan to the AC and Board, and limit our discussion to CDT does not seem appropriate to me.	**Comment received**	Meeting comment - noted.
460					Meeting	12/13/2021	**Sarah Hardgrave**	That was not my suggestion, to limit comments to CDT. It was to submit those comments also directly to the MCWD GSA Board.	**Comment received**	Meeting comment - noted.
461					Meeting	12/13/2021	**Janet Brennan**	How do we do that?	**Patrick Breen:** We have a portal similar to SVBGSA.	Meeting comment - noted.
462					Meeting	12/13/2021	**Janet Brennan**	If this is a recommendation of our entire committee, how do we make that input as a whole committee.	**Patrick Breen:** If the committee in aggregate wants to comment on the entire plan, you can do it in the portal or at our board meeting. **Donna Meyers:** I think if there are comments as a committee for the whole plan, you could refer to that today. Sorry for the confusion.	Meeting comment - noted.
463					Meeting	12/13/2021	**Sarah Hardgrave**	I just want to encourage that comments on the Marina-Ord area go to the MCWD board in addition to our committee comments. Does the MCWD board meet in December?	**Patrick Breen:** Our December meeting is tonight, and will discuss this DWR version tonight. In January it will go forward for Plan Adoption and submittal to DWR.	Meeting comment - noted.
464					Meeting	12/13/2021	**Janet Brennan**	I did hear very positive feedback about the meeting from community members who did attend. Just want to thank staff and Sarah.	**Donna Meyers:** Last Thursday, I also received an invitation from Commercial Property Organization. I did that presentation Thursday and to the M1W Board on November 29. We've had two additional meetings on that area as well.	Meeting comment - noted.
465					Meeting	12/13/2021	**Janet Brennan**	For the plan as a whole, I know that in the Monterey, the Marina-Ord planning area is totally dependent on the plans and programs in the 180/400. Given staff's response on the meaning of "plans" and "subbasins," why doesn't the Marina-Ord part of the plan include the plans and programs of the 180/400 to avoid any confusion regarding implementation of those programs?	**Emily Gardner:** There is language in there that specifically describes supporting the plans from 180/400 and Seaside. It's the most appropriate way forward, but describing someone else's plan is not describing your own plan.	Meeting comment - noted.

466					Meeting	12/13/2021	**Janet Brennan**	This relates to the overall planning process. It seems that integration of all these plans should have been done during the planning of all these GSPs. We'll take another 5 years, and we'll have to revise all the subbasin plans. This seems extremely inefficient, and a waste of time. For the CDT, that depends on getting new water supplies. Based on what AG is willing to support, there is no support to bring in water for the CDT area. I am extremely frustrated by the lack of an integrated planning process, if we ever get to it given the various interests in the AG community to fund basin-wide projects. That is my view of this entire planning process, and I find it very disheartening.	**Donna Meyers:** Yes we talked last Friday. What I would like you to know is that the integrated component across subbasins for integration and implementation is the highest priority for staff. We will literally start in February. We've already scoped a document. This may seem an inefficient way, but we were required by SGMA to complete subbasin plans. Many of these basins, need immediate action and continued feasibility analysis. I realize there is frustration in the water charges framework which seemed like the glue to hold it all together, but after additional conversations, we see starting with allocations as an important stepping stone. We hope to do that immediately. All of this is to say, in year 5 when we update the GSPs, there will be an "integrated' chapter for how these all relate. In the meantime, we need to work with SGMA, get buy-in. We need to get our plans in from local stakeholders. Then as an agency, we have an opportunity to take a closer look in less a planning perspective, and a more integrative perspective. We will continue work in an integrated fashion. We have to. The valley is something that operates in an integrated manner. We need to keep that in our manner of assessing, and we won't lose sight of that. I understand your frustration with the process, and I hope we will get a document that will make sense to you soon.	Meeting comment - noted.
									Gary Petersen: So, to bring some historical context to this, the January submittal marks 7 years we've been at work with SGMA, We completed the 1st four to five chapters of the integrated plan, and then we realized, the necessity of bringing these subbasins together in a coherent manner, we lacked the information to do that without the existence of the subcommittees, that DWR required us to take a different route, because we wanted to do a single plan for the entire basin. That's where we understood the necessity of linking these pieces together and those conversations continued to be ongoing. We lacked the substance to do that at the beginning. We wanted to do a whole basin plan. We also lacked the capacity. Producing these plans has been a remarkable accomplishment. We needed to set the integrated piece on a shelf to get through these plans with a stringent timeline. Having spoken to many people across the state, SGMA was set up to get the plans done. The long-term goal is sustainability. By setting tight deadlines, we had to meet the letter of the law, we had to get these plans done. This left many people frustrated, and left many incapable of producing adequate plans. The plan is getting to the beginning. In my opinion, there was no way to get to an integrated plan while meeting the strict timelines from DWR. No one has ever walked away from the idea of understanding that this valley needs to work together to solve these issues. That's why we ended up here and I understand Janet I read that land watch letters and I've been tracking all that and I don't disagree with a lot of it, but there was just a matter of what was possible at this point. Along the way, because of this, changed the way that water planning is done in Monterey County, and the way we will gather data, and advance this entire process to sustainability.	

467					Meeting	12/13/2021	**Beverly Bean**	I want to comment that we can write plans 'til the cows come home. When the plans are approved, and we don't implement them, what good is it? We have an article in the 180/400 Plan to put a moratorium on new wells in the Deep Aquifer until the Study is completed. It is a priority item. When I brought this to the AC, it was shot down. If the plans are approved, what is the point if they are not implemented. I think it's an exercise in paper-shuffling. In the 180/400 it calls for capital projects, the water charges framework is the way to make it happen. Now we have two subbasins saying they will not participate in the water charges framework, because they are not in overdraft. Now, the 180/400 is unsustainable and cannot pay for these projects because half the valley refuses to participate. Corral de Tierra cannot reach sustainability. We have incredible subsurface flow into the 180/400, which I'm glad to see in the plan admitting that not even if we stop pumping and corral we still can't get to sustainability, because all that water flows into the 180/400, the gradients etc I assume these models are correct. I think we're paper shuffling. I find it very incredibly difficult to put my approval, my yes vote, to send this plan to the State. I'm as frustrated as Janet. I think we need to get real. If we're not going to implement all these wonderful plans we're writing, if that isn't going to happen because of the structure, and the power structure, and the votes, the super majorities that are required; I'm frustrated. The only reason I'm hanging in there is that hopefully we can get the pumping allocations in Corral de Tierra, and coordination with the land use. Just these small things, because I know the capital projects aren't going to happen, because there's no funding. I'm just hanging in there for those things to try and happen. I find it incredibly difficult.	**Donna Meyers:** I will just state that staff is committed to implementation. Friday, I met with SWRCB as well as Senator John Laird. We will continue to seek funding from the state, which is historic surplus at this point with $31BIL, as well as with the $1TRIL Infrastructure Bill, which if focused on water as one of its primary four focuses. which may be a once-a-century opportunity to obtain that kind of resource to bring back to the community. If we are able to bring national and state leaders to the table to understand what needs to get done, which looks to be an insurmountable issue of finance. SGMA requires us to not only look to allocations, which can solve one of our issues, but it also looks to us to actually, but also to remove or eliminate SWI in the 180/400. We do need to accomplish all the criteria that SGMA lays out to meet sustainability in 20yr. I am confident we are getting the attention required from both fed and state leaders, even prior to submission, with regards to the available resources. Will these resources pay for all of it? No, we will need to have local funding. There is a great interest in what we're doing, and I believe that we will be receiving state and federal funding for these kinds of projects. And that is where the state and federal funds really need to be spent, is in the sustainability actions around water supply, drought readiness, and climate change, so I really I appreciate your comments but I do believe that there is a resource through the state and federal infrastructure investment in domestic water that has not occurred in state history. So we'll be going after those resources, and we have been going after those resources over the last 60 days in preparation for being competitive for those kinds of opportunities so we'll keep working on that.	Meeting comment - noted.
468					Meeting	12/13/2021	**Beverly Bean**	In the listing of projects and actions at the end of the plan for CDT, the pumping allocations is first in the list. Does that listing indicate priority? In other words, is pumping allocations the number one thing, because there was some argument about that at the advisory committee about whether the list indicated priority. The second question I have, this implementation of a moratorium, is there any way to have further discussion on this? I don't feel it's been adequately discussed either at the advisory committee or on the board. Why are they not implementing the deep aquifer moratorium? It's a policy issue, it needs to be discussed.	**Donna Meyers:** That item is not noticed today, but I'm happy to chat offline. There will be items on the AC meeting this week that will be of interest. I don't believe I can speak with you about the moratorium. This is not an that's not a noticed item on our agenda for your stakeholder committee. I'm trying to keep track of all these plans, but I don't believe that the allocations reflects a priority, but I would ask Abby or Emily to answer that. **Emily Gardner:** We do reflect that the allocations discussion was a preferred project of the subbasin committee. It's in Chapter 10, below P&MA. Ultimately we'll talk about the subbasin implementation committee that will be formed, and early in 2022 we're going to look at the plan look at the projects and management actions, including allocations that are included in the plan, and talk about the funding that's needed, and talk about the costs/benefits, and the next steps, and that subbasin implementation committee will be the ones to get the projects rolling.	Meeting comment - noted.
469					Meeting	12/13/2021	**Sarah Hardgrave**	I think our committee has been clear on a couple different occasions that allocations were the highest priority. We made motions to that effect, and that is a clear statement from the committee. We have not made any motion on the prioritization of the other projects. Each of those is the nominal amount of supplemental supply for a lot of money, and those will be hard conversations.	**Comment received**	Meeting comment - noted.
470					Meeting	12/13/2021	**Margaret-Anne Coppernoll**	When I opened the plan, I was just blown away by how fantastic it is. You have all done a great job of putting this together, and it was a complex undertaking. Like any plan, getting to the implementation phase, you will always have changes that occur. I do agree that allocations of pumping should be a priority, as that will be a first step to get people to conserve. This is a fantastic way to take a detailed look at where we are, and energetically come up with solutions. I think the plan is a great way to do that. I want to tell everybody on this committee, and you've done a fabulous job, and this plan is phenomenal. I think there are issues with self-reporting, but I think well registration may cover that for details on what's pumped out. I want to thank you all for everything, and Merry Christmas and Happy New Year if I don't't see you all. I think a lot can be carried over in implementation for operational decisions, on the ground where it really counts.	**Comment received**	Meeting comment - noted.

471					Meeting	12/13/2021	**Max Storms**	I appreciate the work done. We are the largest water purveyor in the basin, so it's important to us to keep an eye on things for our own planning. For the most part, we have a lot of interest in the Salinas Valley. It's been very informative to be on this committee. We've just been trying to follow along. Thank you.	**Comment received**	Meeting comment - noted.
472					Meeting	12/13/2021	**Ron Stefani**	I think great job by staff. I think Margaret said it best, this is a plan, and once we start implementing it, it will be tweaked. No one is going to fund anything until you know what you're funding. Everyone will say no until we know what we're getting. Thank you.	**Comment received**	Meeting comment - noted.
473					Meeting	12/13/2021	**Patrick Breen**	I would like to echo some of the points made. I want to extend my appreciation for everyone collegial nature to get this done. I know there have been disagreements. It's been refreshing to see the camaraderie to get this together. It's going to be critical to continue that camaraderie moving forward. It will be critical that our neighbors succeed. Thank you.	**Comment received**	Meeting comment - noted.
474					Meeting	12/13/2021	**Norm Groot**	I want to address some of the comments expressed here today on moving forward. I want to point out 'what happens if we don't have a plan?'. I think we need to consider the alternatives here. And we're seeing what will happen to some of those GSPs that have been deemed inadequate. If we submit a plan, and we admit it's not perfect, but it's really consensus-building and will be refined as we go along. We've been saying that for months. We need to maintain that local control. This may not be the optimal plan, the alternative is worse. Let's keep local control. I just want to make sure we're looking at the larger perspective here if we don't have a plan to submit in January.	**Comment received**	Meeting comment - noted.
475					Meeting	12/13/2021	**Janet Brennan**	I'm prepared to make a motion to forward this to the Advisory Committee.	**Comment received**	**MOTION PASSES UNANIMOUSLY**

477					Meeting	12/13/2021	**Sarah Hardgrave**	I have appreciated the opportunity to participate in this committee. We've had some very robust discussions in the last year and a half. This has been a very important exercise in looking at the CDT management area. We've talked a number of times about the past studies, and it's been known for a long time that this is an area that has GW sus issues. This process has shined a light on the particular challenges this area faces in a new and different way. The GeoSyntec report was done over a decade ago, and never implemented, acknowledging Beverly's point that there have been previous plans not implemented. Under SGMA, we have additional tools, both carrots and sticks, to address this particular area we've been focused on. Our particular concerns, that cross outside of this management area, are driven by the specific issues of this area. This area is unique considering the urban/ag division, compared to the rest of the Basin. It does make for unique and specific challenges. Moving forward, the priority in addition to allocations and controls, does need to be DW controls and constraints. By my estimation, ~3,500 unique connections, or roughly 7,000 people dependent on groundwater supplies in the Corral de Tierra area. That's substantial, so moving forward with het integrated implementation actions, the integration committee should focus on DW issues and purveyors, including MCWD, and Castroville CSD, and so on; I think that is a very important area of focus moving forward. That is of utmost importance in this area. I don't believe this area can solve its issues without participating in regional DW solutions. Supply for people for DW in their homes in an area where we have two regulated utilities, 30-50 mutual water companies, and 160 different domestic well owners, we just have a unique situation.	**Comment received**	Meeting comment - noted.
								I think we've come up with some good options, but the implementation phase of this plan will be critical. We definitely need to get the word out there on these issues. Moving forward on implementation, I hope we get broader representation of actual managers of the small water systems as well as domestic well owners. It's been helpful to have Max here, but there are a lot of other folks involved that I hope engage moving forward. Lastly, my observation on the comments received on the plan, were comments made across all the GSPs. Or the ones specific to the Monterey Subbasin, were more about the Marina-Ord area. For the subbasin as a whole, this really is a subbasin that needs to coordinate with its neighbors to reach sus. The importance of collab with MCWD to address issues in the 180/400 came out to me as an important thing moving forward. If this plan says the Marina-Ord is sus if the 180/400 is sus, that's a heavy lift, and we have to all be at the table together. I concur with your comments on integration, Janet, and the importance of it. For Seaside, I was involved in the early years of the adjudication. If it had not been for the adjudication, that would be another Salinas Valley GSP. The Monterey Subbasin is the bridge to the peninsula, and there is incredible politics around water on the peninsula. I think the Seaside Watermaster needs to be at the table with implementation. We have invested quite a bit in water projects for the peninsula. I have concerns about risk for SWI in Seaside and monitoring along that boundary. The hydrogeology along that boundary was in question then. Now with SGMA, we can work on it further. The boundary with the Laguna Seca will be one of the most important areas of study going forward. I hope everyone stays engaged. This is not a plan that can be put on a shelf; we have to take action to address these issues.		
								If the conditions in the CDT area are described to DWR as they are in the plan, it would have been a critical area, not medium priority. The specific actions that need to be taken will be really important.		
480					Meeting	12/13/2021	**Beverly Bean**	Am I correct that you have to live or work in the Basin in order to be in the implementation committee?	**Emily Gardner:** That is what the Board voted on, yes.	Meeting comment - noted.

481					Meeting	12/13/2021	**Janet Brennan**	I represent LandWatch, which is county-wide, which I believe counts as work.	**Emily Gardner:** On that logic, I believe yes. It's not an organization seat, but an individual person. So if an individual person works for that organization and joins, and that organization represents the area, that's different. **Donna Meyers:** I would ask Marina. The other thing is that Janet, you are on the Board as well. I would ask Marina to clarify. **Marina Pantchenko:** The Board voted that individuals must reside or work in that area.	Meeting comment - noted.
482					Meeting	12/13/2021	**Janet Brennan**	Well, I prepared an application this morning, so we'll find out. But you have to be on a subcommittee to be on the implementation committee, is that correct? I would have to be on the Monterey Basin to be on the implementation committee?	**Emily Gardner:** Each subbasin will have an implementation committee to receive updates and move forward. We will also have an Integrated committee, and those folks will weigh in on multi-subbasin projects, and valley-wide implementation steps.	Meeting comment - noted.
483					Meeting	12/13/2021	**Sarah Hardgrave**	For this subbasin, will there be an opportunity for a representative from each Management area? It seems like we would need that because of the distinct issues facing each area.	**Emily Gardner:** We have a few other suggestions for the Integration Committee, that we can take to the Board. Right now, it's the MCWD GSA is on that committee, but not necessarily a stakeholder in that area. Similar for the Arroyo Seco GSA. We can forward this suggestion along to the board.	Meeting comment - noted.
484					Meeting	12/13/2021	**Sarah Hardgrave**	I would encourage sending out a notice of this implementation committee to your list of all the mutual water companies and domestic well owners as much as you have a list. I would like to see more of the small water systems engaged. I think this will be important for moving forward. We're not describing specific seats, I want folks to know about this opportunity.	**Emily Gardner:** We can send it to the same folks we invited to the stakeholder outreach event. And you can send it to your list as well. If you all could forward it along to your lists, we would really appreciate it. **Patrick Breen:** Can we just be clear about what implementation means, geographically? I just want to be really clear.	Meeting comment - noted.
485					Meeting	12/13/2021	**Sarah Hardgrave**	Are you planning to do anything like this for the Marina-Ord area? Generally, our Board is our GSA board. We're in discussion now about whether we want some stakeholder group. We're still determining that.	**Comment received**	Meeting comment - noted.
486					Meeting	12/13/2021	**Beverly Bean**	Is this implementation committee going to be just Corral, or will it include MCWD?	**Patrick Breen:** We need to be clear that we're talking about two different GSAs. This committee is a part of the SBVGSA. The MCWD GSA is the responsible area for the Marina-Ord area.	Meeting comment - noted.
487					Meeting	12/13/2021	**Beverly Bean**	As we solicit applications for the Implementation, does that include the Marina-Ord area, members from that to be on this implementation committee, or is it just referring to Corral?	**Donna Meyers:** It's just Corral because of the two different agencies.	Meeting comment - noted.
488					Meeting	12/13/2021	**Sarah Hardgrave**	As helpful as it's been to have Patrick on this committee here for coordination, I would encourage MCWD GSA to have someone on the implementation committee for coordination purposes.	**Patrick Breen:** We'll take that consideration under advisement and figure out how we're going to approach our implementation governance and decision.	Meeting comment - noted.

Appendix 3-A

1993 and 1996 Annexation Agreements

MCWRA/U.S. Army, 1993. Agreement No. A-06404 - Agreement between the United States of America and the Monterey County Water Resources Agency Concerning Annexation of the Fort Ord Into Zones 2 and 2A of the Monterey County Water Resources Agency, dated September 1993.

MCWRA/MCWD, 1996. Annexation Agreement and Groundwater Mitigation Framework for Marina Area Land, dated March 1996.

AGREEMENT NO. A-06404

AGREEMENT BETWEEN THE UNITED STATES OF AMERICA AND THE MONTEREY COUNTY WATER RESOURCES AGENCY CONCERNING ANNEXATION OF FORT ORD INTO ZONES 2 AND 2A OF THE MONTEREY COUNTY WATER RESOURCES AGENCY

This Agreement is entered into this 21st day of September, 1993, by and between the Government of the United States of America ("Government"), represented by the United States Army, and the Monterey County Water Resources Agency ("MCWRA"), a political subdivision of the State of California, represented by the Monterey County Board of Supervisors.

1. Purpose and Authority:

a. Purpose: The purpose of this agreement is to provide the terms and conditions under which the Fort Ord Lands will be annexed into the Zones.

b. Authority:

(1) By California law, the MCWRA is responsible for managing the surface water and groundwater resources in the Salinas Valley and providing flood control and water conservation services throughout Monterey County. The authority for the MCWRA to enter into this agreement is cited in California Water Code, Appendix 52-43 (Appendix "A"). The MCWRA has the authority to annex the Fort Ord Lands overlying the Seaside Basin based on a Memorandum Of Agreement between the MCWRA, the MPWMD, and the Pajaro Valley Water Management Agency, dated May 10, 1993 (Appendix "B").

(2) The authority for the Government to enter into this agreement was provided in Public Law 101-510 (National Defense Authorization Act for Fiscal Year 1991), Section 2101, dated November 5, 1990 and amended by Public Law 102-190 (National Defense Authorization Act for Fiscal Years 1992 and 1993), Section 2702, dated December 5, 1991. The funding for the Government to enter into this agreement was provided by Public Law 101-519 (Military Construction Appropriations Act, 1991), dated November 5, 1990.

2. Definitions:

a. United States Army Engineer District, Sacramento, California ("Corps"): A field operating agency of the Army Corps of Engineers, a major command of the Army; the agency that will execute this agreement on behalf of the Government;

b. Fort Ord: An existing Army installation in north Monterey County currently operating under the Army Forces Command; Fort Ord will realign to an enclave under provisions of Public Law 101-510 (Defense Base Closure and Realignment Act of 1990); on October 1, 1994, this installation will no longer be known as Fort Ord and will instead be known as the Presidio of Monterey Annex under the Army Training and Doctrine Command; disposal of excess Fort Ord property pursuant to Public Law 101-510 could begin before October 1, 1994 provided the Army has issued a Record of Decision on the Environmental Impact Statement for the Disposal and Reuse of Fort Ord; parts of Fort Ord were leased on a long term basis prior to the realignment decision;

c. Presidio of Monterey Annex ("POM Annex"): The proposed residual military mission enclave remaining on Fort Ord after its realignment; this annex shall continue operations in support of the Department of Defense and other federal agencies in the Monterey Peninsula area; the boundaries of the POM Annex should be finalized by early 1994;

d. Presidio of Monterey ("POM"): An existing Army installation in Monterey County operating under the Army Forces Command; on October 1, 1994, will be under the Army Training and Doctrine Command; POM is the home of the Defense Language Institute; POM will also be responsible for the proposed POM Annex;

e. Reserve Center ("RC"): An existing Army Reserve Center located on 12 acres of Fort Ord not contiguous to the POM Annex; the RC will remain after the realignment of Fort Ord;

f. Fort Ord Lands: A term denoting all lands within the existing boundaries of Fort Ord including: property needed to support the Army's future mission requirements (POM Annex and RC); property under a long term lease; property awaiting disposal either in a caretaker status or under an interim lease; and property already disposed;

g. Salinas Basin: The Salinas River Groundwater Basin; the Salinas Basin generally underlies the northwestern portion of Fort Ord;

h. Seaside Basin: The Seaside Groundwater Basin; the Seaside Basin generally underlies the southwestern portion of Fort Ord;

i. Monterey Peninsula Water Management District ("MPWMD"): A California Special District created by the State Legislature in 1978 having water management authority over the Seaside Basin;

j. Project: A future, long term, reliable, potable water system for the POM Annex/RC and other areas; the Project will provide at least 6,600 acre-feet per year which will permit all Salinas Basin wells on Fort Ord Lands to be shut down except during emergencies; stopping all pumping from the Salinas Basin on Fort Ord Lands is necessary to mitigate seawater intrusion; the MCWRA is currently developing such a Project to supply water to the Fort Ord Lands, Marina, Salinas, Toro Park, and perhaps other areas in north Monterey County; it is also possible that another water agency, district, utility, or purveyor could develop a smaller scale Project to supply water for just the Fort Ord Lands;

k. Project Implementation: The potable water system cited in paragraph 2.j. shall be considered "implemented" upon both the completion of construction and the delivery of potable water to POM Annex/RC from the completed water system;

l. Zones: Zones 2 and 2A of the MCWRA which are the zones of benefit for the MCWRA Nacimiento and San Antonio Dams, respectively.

3. <u>Problem and Scope:</u>

a. Fort Ord overlies two groundwater basins, the Salinas Basin and the Seaside Basin. See Appendix "C" for a map. Most of the installation's facilities and all of its potable wells overlie the Salinas Basin. The portion of the installation which overlies the Seaside basin has less development consisting mostly of family housing and recreational facilities. Fort Ord's only active well in the Seaside Basin is a non-potable well to irrigate the golf courses. Fort Ord's peak annual withdrawal from the Salinas basin from 1980 to 1992 was 6,600 acre-feet in 1984; and the peak withdrawal from the Seaside Basin from 1986 to 1989 was 424 acre-feet in 1989.

b. The Salinas Basin has had a problem with seawater intrusion since the 1940's. Seawater intrusion occurs when groundwater levels fall below sea level. This is caused by pumping more water out of an aquifer than is being recharged into it. Pumping by Fort Ord has contributed to this problem, but only to a limited extent as the Fort Ord pumping from the Salinas Basin from 1988 to 1992 averaged only 5,200 acre-feet per year and the estimated Salinas Basin overdraft (amount that pumping exceeds recharge) is about 50,000 acre-feet per year. Seawater intrusion has forced the abandonment of many wells along the coast, and required Fort Ord to relocate their well field inland in 1986. In contrast to the Salinas Basin, the Seaside Basin appears to be in a nearly balanced condition.

c. Because of the magnitude of the seawater intrusion problem, a regional solution is needed. Without a regional solution, Fort Ord's remaining potable wells will eventually become contaminated by seawater. The MCWRA is developing a Project to provide a regional water supply system. The MCWRA is also developing the Castroville Sewage Reclamation/Irrigation Project. Both of these projects are intended to mitigate the effects of seawater intrusion in the Salinas Basin.

d. As long as there is an Army enclave on Fort Ord Lands, the Army will need a reliable potable water supply. In view of the limited life of Fort Ord's remaining potable wells, annexation is prudent because it will permit access to water produced by a future MCWRA project. Additionally, annexation will facilitate the disposal and reuse of Fort Ord Lands, and enhance the market value of any property which is sold. This is because, without annexation, the existing Salinas Basin overdraft could significantly limit the water rights of Fort Ord Lands except for the POM Annex/RC.

e. There have been questions raised over Fort Ord's right to withdraw groundwater from the Salinas Basin. Fort Ord/POM Annex/RC claim certain legal rights to the use of water from the Salinas Basin due to their federal status. However, the MCWRA claims limited regulatory authority over Fort Ord/POM Annex/RC's use of Salinas Basin water with respect to withdrawals of polluted or contaminated groundwater; and the MCWRA also claims ownership rights over water used by Fort Ord/POM Annex/RC which is released into the Salinas Basin from the Nacimiento and San Antonio Dams. Annexation and the terms of this agreement will clarify the water rights of both parties.

4. Terms and Conditions:

a. Execution of this agreement, which includes the Annexation Assembly and Evaluation Report (Appendix "D"), shall be deemed to be a petition by the Government, as the present owner of all Fort Ord Lands, to permit the annexation of the Fort Ord Lands by the MCWRA into Zones 2 and 2A. The MCWRA shall thereafter promptly commence proceedings for such annexation, and will diligently and in good faith pursue such annexation proceedings to completion.

b. The parties have discussed and agreed on payment of a fee by the Government totaling $7,400,000, as authorized by Public Law 101-510 and appropriated by Public Law 101-519. The basis for this fee is discussed in section IV.F.1. of the attached Annexation

Assembly and Evaluation Report. Fort Ord will be annexed into the Zones in consideration of the payment of the fee. The Government shall have no further financial responsibility or obligation of any kind to the MCWRA with respect to existing water project costs, e.g., Nacimiento and San Antonio Reservoirs. Further, the MCWRA releases the Government from any and all claims related to Fort Ord's groundwater withdrawals from the Salinas Basin prior to this agreement, and from any claims related to any Government action that may have caused or contributed to seawater intrusion in the Salinas Basin.

c. After execution of this agreement and until Project Implementation, Fort Ord/POM Annex/RC may withdraw a maximum of 6,600 acre-feet of water per year from the Salinas Basin, provided no more than 5,200 acre-feet per year are withdrawn from the 180-foot aquifer and 400-foot aquifer. The 6,600 and 5,200 acre-feet thresholds correspond to the annual peak (1984) and recent average (1988-1992) amounts of potable water Fort Ord has withdrawn from the Salinas Basin (does not include pumpage from the non-potable golf course well in the Seaside Basin). Groundwater withdrawals from the Salinas Basin by Fort Ord/POM Annex/RC for the purpose of environmental restoration shall not count toward the 6,600 and 5,200 acre-feet thresholds. Additionally, groundwater withdrawals from the non-potable golf course well shall not count toward the 6,600 and 5,200 acre-feet thresholds because this well is located in the Seaside Basin. The MCWRA agrees not to object to any Fort Ord/POM Annex/RC withdrawal under 6,600 acre-feet per year, except in compliance with California Water Code Appendix, Chapter 52, Section 22. If the MCWRA is concerned about a withdrawal, the MCWRA will first notify the Fort Ord/POM Annex Commander. The parties agree to make every effort to first resolve seawater intrusion disputes through mutual agreement. In any event, the MCWRA, after notice from the Fort Ord/POM Annex Commander, will not object to withdrawals in support of war, national emergency, contingency operation, troop mobilization, or unexpected mission requirements, and such withdrawals shall not count toward the 6,600 and 5,200 acre-feet thresholds. The Government will develop a water conservation program at Fort Ord/POM Annex/RC and will institute, in its discretion, measures to conserve water. The Government will participate in MCWRA water conservation initiatives and programs as mutually agreed by the parties.

d. Until Project Implementation, Fort Ord/POM Annex shall have exclusive ownership and operation of potable wells #24, #29, #30, #31, #32, Jacks well, and Pilarcitos well in the Salinas Basin, and the non-potable golf course well #1 in the Seaside Basin. See Appendix "C" for the locations of these wells. Jacks well, Pilarcitos well, and well #24 are inactive; well #32 has recently failed; and the rest are active. The MCWRA agrees not to object to Fort Ord/POM Annex/RC replacing any existing well or adding any new well on Fort Ord Lands subject to the conditions described in paragraph 4.c. above. Also until Project Implementation, Fort Ord/POM Annex/RC shall be the sole user of the aforementioned wells, provided that the Government, in its sole discretion, may permit the use of the Salinas Basin wells by others for use on Fort Ord Lands, or may provide water from the Salinas Basin wells to others on Fort Ord Lands in connection with any reuse plans. The Government shall retain all reasonable and necessary utilities and reserve all necessary easements to operate and maintain all Fort Ord/POM Annex/RC wells. After Project Implementation, Fort Ord/POM Annex shall retain ownership of the aforementioned wells, and the Government agrees to stop pumping from the Salinas Basin wells except for an emergency such as fire fighting or a situation as described at the end of paragraph 4.c. above. Project Implementation shall be no cause to curtail or stop pumping from any Seaside Basin well on Fort Ord Lands.

e. The Government will not pay any MCWRA assessments (such as standby charges, water delivery charges, water project assessments, etc.) until a MCWRA developed Project is implemented. This applies to not only the portions of Fort Ord retained by the Army, but also to any other portions of Fort Ord transferred to federal entities. See paragraphs 4.j.(3) and 4.j.(4) for a discussion of these future assessments.

f. The annexation into the Zones shall provide the Government with appropriate representation in Zone administration and decision making.

g. Should future litigation, regulation or other unforeseen action diminish the total water supply available to the MCWRA, the MCWRA agrees that it will consult with the Fort Ord/POM Annex Commander. Also, in such an event, the MCWRA agrees to exercise its powers in a manner such that Fort Ord/POM Annex/RC shall be no more severely affected in a proportional sense than the other members of the Zones.

h. If prior to Project Implementation, any Fort Ord/POM Annex well (including any located in the Seaside Basin) becomes contaminated with seawater, or is adversely affected by regulatory or legal action, the MCWRA: shall cooperate with the Government in finding an interim water supply; shall assist the Government in any permit processes necessary to obtain such an interim water supply; and shall provide the same services to the Government as it would to any other municipal water supplier in the Zones under similar circumstances. The Government will bear the costs of obtaining such an interim water supply. Such costs will not include the cost of MCWRA staff time in providing services to the Government hereunder. The MCWRA will continue to monitor the rate of seawater intrusion, and will keep the Fort Ord/POM Annex Commander informed as to: the rate of seawater intrusion; the progress of plans for its Project; and the estimated remaining life of the Fort Ord/POM Annex wells. The MCWRA shall pass to the Fort Ord/POM Annex Commander any information they may obtain related to the continuing yield of Fort Ord/POM Annex wells located in the Seaside Basin.

i. As part of the disposal of Fort Ord, the Government is considering transferring the ownership and operation of the Fort Ord wells and water distribution system to a successor water purveyor, utility, or agency. Under such a transfer, the MCWRA agrees that the Government, in its sole discretion, may transfer its applicable water rights under this agreement to the successor water purveyor, utility, or agency. The MCWRA also agrees not to object to such a successor obtaining or developing a water supply from outside the Salinas Basin for the Fort Ord Lands.

j. If the opportunity arises and it is in the Government's best interests, the Government, in its sole discretion, may participate in a Project developed by an organization other than the MCWRA. In any event, Government participation in a MCWRA developed Project would be contingent on the following:

(1) The MCWRA shall, upon Project Implementation, continue to provide water and related services to Fort Ord/POM Annex/RC and shall provide for Government representation in MCWRA decisions affecting Fort Ord/POM Annex/RC, and in MCWRA's administration of the Project.

(2) The water allocation to be made available to POM Annex/RC from the Project shall be based only on the water needed to support the Army's future, long term mission requirements, or as otherwise agreed to by the parties. By the time of Project Implementation, all excess Fort Ord Lands should have been disposed. The water allocation to be made available to the disposed property from the Project shall be an issue between these property owners and the MCWRA.

(3) The capital cost for the Project shall be distributed among all properties within the Zones in an equitable manner. The Government would favorably consider a funding plan similar to the MCWRA's proposed funding plan for the Castroville Sewage Reclamation/Irrigation project in which approximately 50 percent of the capital cost is funded by the MCWRA members receiving the water, and 50 percent is funded by other members in

the Zones. An acceptable funding plan will also require that the capital cost paid by each member receiving water from the Project generally be proportional to their water allocation from the system. In any funding plan, the Government will reserve the right to pay the capital cost through either periodic assessments, or by a lump sum amount. The Government does not intend to be a party to any agreement in which military appropriations fund an inequitable portion of the capital cost of the Project. The $7,400,000 annexation fee shall not count toward the Government's share of the Project's capital cost.

(4) The MCWRA's cost to operate and maintain (O&M) the Project should be distributed on the basis of water usage or allocation. If the MCWRA proposes to distribute O&M costs on the basis of property area, then the Government only intends to pay such an assessment and any applicable standby charges on the Fort Ord Lands needed to support Army missions, i.e., POM Annex and RC. The Government will not pay O&M assessments or standby charges for any Fort Ord property in a caretaker status awaiting disposal. Any federal entities which have acquired portions of Fort Ord will not pay standby charges on property which is unsuitable for development.

(5) Prior to either the initiation or commitment of any military appropriations to the Project by the Government, the MCWRA shall complete all appropriate feasibility studies and environmental reviews. With respect to only Fort Ord Lands under Army control, participation in the Project, or any other water supply project is subject to compliance with applicable federal laws and regulations, e.g., Army Regulation 420-41 and Federal acquisition regulations; and subject to final review and approval by the Government.

(6) As Fort Ord/POM Annex/RC will, upon Project Implementation, rely on the MCWRA's ability to provide potable water, the MCWRA shall defend the rights of Fort Ord/POM Annex/RC to a water supply upon implementation of the Project as though those rights were its own.

5. <u>Funding:</u>

a. The Government hereby obligates, pursuant to section 2702 of Public Law 102-190, $7,400,000 for the annexation fee, the basis of which is set forth in Appendix D, section IV.F.1. Upon completion of the annexation, the Government shall make payment to the MCWRA in the amount of $7,400,000.

b. The $7,400,000 annexation fee shall be the maximum Government payment in consideration for the annexation of the Fort Ord Lands and the execution of this agreement.

c. The parties recognize that this agreement is subject to the availability of funds provided by Congress.

6. Duration of Agreement:

a. If the Government decides to participate in a Project developed by an organization other than the MCWRA pursuant to paragraph 4.j. of this agreement, the MCWRA agrees to either terminate this agreement or negotiate modifications to it if so requested by the Government.

b. In the event the Army ends its presence at Fort Ord, the MCWRA agrees to either terminate this agreement or negotiate modifications to it if so requested by the Government.

c. If Fort Ord has not been annexed to the Zones by September 30, 1995, the MCWRA agrees to either terminate this agreement or negotiate modifications to it if so requested by the Government.

d. If the MCWRA has not achieved reasonable progress by December 31, 1999, toward implementation of a MCWRA developed project; or a MCWRA developed Project has not been implemented by December 31, 1999, and the Government is not convinced that the MCWRA can achieve Project Implementation within a time frame deemed reasonable by the Government, then the MCWRA agrees to either terminate this agreement or negotiate modifications to it if so requested by the Government.

e. In the event this Agreement is terminated before the annexation has been completed, the MCWRA, in its sole discretion, may continue with the annexation; however, in such circumstance, the Government shall not make any payment for such annexation. In the event this agreement is terminated after the Fort Ord Lands have been annexed into the Zones, the Government will not demand return of the payment. In the event this agreement is terminated by the Government pursuant to any of the above conditions, the MCWRA agrees not to file any claim against the Government related to the termination.

SUBJECT: Annexation of Fort Ord into Zones 2 and 2A of the Monterey County Water Resources Agency

7. Binding on Successors: This agreement shall be binding upon and shall inure to the benefit of the non-federal successors and assigns of the Government's interest in the property now known and referred to as Fort Ord, California, except that this agreement shall not exempt any such non-federal successor or assign, whether of fee title or some lesser interest in the property, from any ordinance or other regulation enacted by the MCWRA or from any assessment, charge, tax, or other monetary exaction levied by the MCWRA. All such non-federal successors and assigns shall be subject to regulation and be subject to assessment, charge, tax, or other monetary exaction to the extent allowed by law at the time such enactment or levy is in effect.

FOR THE UNITED STATES OF AMERICA

Michael W. Owen

Acting Assistant Secretary of the Army for Installations, Logistics and Environment

- C - Location of the Existing Wells
- D - Annexation Assembly and Evaluation Report

§ 52-43. Annexation to zones

Sec. 43. (a) In addition, or as an alternative, to the procedures for amending zones described in Section 7, any territory in the agency lying within the watershed within which a zone is situated may be annexed to that zone pursuant to this section. Territory which is in, or annexed to, one zone may be annexed to another zone pursuant to this section.

(b) The following applies with respect to the annexation of new territory to any zone pursuant to this section:

(1) (A) A petition for annexation by election signed by 25 percent of the freeholders residing in the territory proposed to be annexed as shown by the last equalized assessment roll of the county shall be presented to the board.

(B) The petition shall designate specifically the boundaries of the territory proposed to be annexed and its assessed valuation as shown by the last equalized assessment roll and shall ask that the territory be annexed to the zone. The petition shall be accompanied by a bond in the sum of not less than one hundred dollars ($100), to be approved by the board and filed with the clerk of the board as security for the payment by the petitioners of the reasonable cost of the election on annexation, in the event that at the election less than a majority of the votes cast are in favor of annexation. The petition shall be verified by the affidavit of one of the petitioners.

(C) The petitioner shall be published by the petitioners for at least two weeks preceding its hearing in a newspaper of general circulation published in the zone, if there is one, or, if not, in a newspaper of general circulation published in the agency, together with a notice stating the number of signers of the petition, the time when the petition will be presented to the board and that all persons interested may appear and be heard. It shall not be necessary to publish the names of the signers.

(D) At the time specified for the hearing, the board shall hear the petition and may adjourn the hearing from time to time. Upon final hearing of the petition, the board, if it approves the petition as originally presented or in a modified form, shall make an order describing the exterior boundaries of the territory proposed to be annexed and ordering that an election be held in such territory for the purpose of determining whether or not the territory shall be annexed to the zone. The order shall fix the day of the election, which shall be within 60 days from the date of the order, and shall show the boundaries of the territory proposed to be annexed to the zone and shall set forth the measure to be submitted to the voters of such territory and shall designate the precincts, polling places and election officers for such election and state the times between which the polls shall be open. The order shall be published pursuant to Section 6066 of the Government Code. This order shall be entered in the minutes and is conclusive evidence of a due presentation of a proper petition, and of the fact that each of the petitioners was, at the time of the signing and presentation of the petition, qualified to sign.

(E) The election shall be held and conducted as provided in Chapter 1 (commencing with section 22000) of Part 1 of Division 12 of the Elections Code and sample ballots and polling place cards shall be mailed as provided in section 10012 of the Elections Code. If a majority of the votes in the territory proposed to be annexed at an election called therein by the board for that purpose are in favor of the annexation, the clerk of the board shall make and cause to be entered in the minutes and endorsed on the petition an order approving the petition and the petition shall be filed. The entry is conclusive evidence of the fact and regularity of all prior proceedings of every kind required by law and of the facts stated in the entry. The board at its next regular meeting after the entry shall, by an order, alter the boundaries of the zone and annex to it the territory described in the petition. The order of the board is conclusive evidence of the validity of all prior proceedings leading up to the annexation and recited in the order, and from and after the order the territory is part of the zone. If, at the election, less a majority of the votes in a territory proposed to be annexed are in favor of the annexation of the territory to the zone, the signers of the petition shall, within 10 days after the canvassing of the votes of the election, pay to the board the reasonable cost of the election and, if not paid within 10 days, the board may sue on the bond to recover the cost of the election. If the result of the election is against annexation, the board shall, by order, disapprove the petition and enter the order in its minutes. No other proceeding shall be taken in relation thereto until the expiration of six months from the presentation of the petition, except to collect the costs of the election.

APPENDIX A

(2) (A) A petition for annexation without election signed by the owners of real property in the territory proposed to be annexed which real property represents at least 75 percent of the total assessed valuation of real property in the territory as shown by the last equalized county assessment roll, shall be presented to the board.

(B) The petition shall designate specifically the boundaries of the territory and the assessed valuation of real property therein as shown by the last equalized county assessment roll and shall show the amount of real property owned by each of the petitioners and its assessed valuation as shown by the last equalized county assessment roll. The petition shall ask that the territory be annexed to the zone. The petition shall be verified by the affidavit of one of the petitioners.

(C) The petition shall be published by petitioners at least two weeks preceding the hearing in a newspaper of general circulation published in the zone, if there is one, or, if not, in a newspaper of general circulation published in the agency. With the petition there shall be published a notice stating the number of signers of the petition, the time when the petition will be presented to the board and stating that all persons interested may appear and be heard. It shall not be necessary to publish the names of the signers. A printed copy of the petition and notice as so published shall be mailed pursuant to Sections 53520 to 53523, inclusive, of the Government Code.

(D) At the time designated the board shall hear the petition and any person interested, and may adjourn the hearing from time to time. Upon the hearing of the petition, the board shall determine whether or not it is in the best interests of the zone and the territory that the territory be annexed to the zone and the board may modify the boundaries of the territory proposed to be annexed as set forth in the petition by decreasing the area of the territory. If the board upon final hearing determines that it is in the best interests of the zone and of the territory proposed to be annexed that the territory be annexed, it shall make an order describing the boundaries of the territory proposed to be annexed and shall alter the boundaries of the zone and annex to it the territory described in the petition and the territory is then a part of the zone.

(3) A petition for annexation without election signed by 100 percent of the owners of real property in the territory proposed to be annexed may be presented to the board. The petition shall designate specifically the boundaries of the territory and shall ask that the territory be annexed to the zone. The petition shall be verified by the affidavit of one of the petitioners. The board shall determine, upon reviewing the petition, whether or not it is in the best interest of the zone and the territory that the territory be annexed to the zone. The board may modify the boundaries of the territory proposed to be annexed as stated in the petition by decreasing the area of the territory. If the board determines that it is in the best interest of the zone and of the territory proposed to be annexed that the territory be annexed, the board shall make an order describing the boundaries of the territory proposed to be annexed and shall alter the boundaries of the zone and annex to it the territory described in the petition, and the territory is then a part of the zone.

(4) No petition or request for annexation pursuant to paragraphs (1) to (3), inclusive, may be accepted by the board if a zone annexation petition involving any of the same territory is pending before it for annexation to the same zone.

(5) An order for annexation may be by ordinance or resolution. Whenever any new territory is annexed to a zone, the territory thereupon becomes subject to all the liabilities and entitled to all the benefits of the zone. Any order for annexation may provide for, or be made subject to, the payment of a fixed or determinable amount of money for the acquisition, transfer, use, or right of use of all or any part of the existing property, real or personal, of the zone. The board may provide that payment of the amounts shall be either: (1) in lump sums or (2) in semiannual installments with interest thereon at a rate not to exceed 12 percent over a period not to exceed 10 years beginning on July 1 following the next succeeding March 1. If the payment is in semiannual installments, the board shall provide in the ordinance that the total of each sum to be paid by each parcel shall constitute a lien on the parcel as of noon on the next succeeding March 1, the same as the lien for general agency and zone taxes; that the semiannual installments shall be paid and collected at the same time and in the same manner and by the same persons as, and together with and not separately from, general agency and zone taxes and shall be delinquent at the same time and thereafter subject to the same thereafter sell, lease, or otherwise dispose of the property in the manner prescribed by law for counties.

(Stats.1990, c. 1159 (S.B.2580), § 41.)

A

ADDENDUM NO. 1 TO
MEMORANDUM OF AGREEMENT BETWEEN
THE MONTEREY COUNTY WATER RESOURCES AGENCY,
THE MONTEREY PENINSULA WATER MANAGEMENT DISTRICT AND
THE PAJARO VALLEY WATER MANAGEMENT AGENCY

This is Addendum No. 1 to the memorandum of agreement (MOA) between and among the Monterey County Water Resources Agency (MCWRA), the Monterey Peninsula Water Management District (MPWMD) and the Pajaro Valley Water Management Agency (PVWMA), dated December 15, 1991. The date of this addendum for reference purposes is September 28, 1992.

RECITALS

This addendum to the MOA is entered into in light of the following facts:

A. MCWRA is developing a Seawater Intrusion Program (SIP) to mitigate the effects of seawater intrusion into the groundwater basin along the coast under Ft. Ord, Marina, and the Castroville area. This program has been in the planning stages for several years. As part of this program, it has been proposed that pumping from existing groundwater wells supplying Fort Ord and the Marina County Water District (MCWD) be curtailed or eliminated, the construction of additional wells in the seawater intrusion area be limited or prohibited, and a replacement potable water supply be provided to Fort Ord and the MCWD by MCWRA, from wells to be constructed in the Salinas Valley. In order to control pumping from existing wells, MCWRA may acquire the existing wells. MCWRA may at some time seek to levy assessments within the subject area, to impose charges for water provided to the subject area, and to raise revenues from within the subject area in other ways, in order to operate, maintain, and improve the SIP in that area. MCWRA decisions on whether to proceed with this project will be made in the future.

B. MPWMD has an interest in this part of the SIP, in that part of Fort Ord and adjacent areas are within MPWMD's boundaries. Nevertheless, MPWMD does not wish to participate in the SIP, and does not wish to impede its implementation.

C. The impending closure of Ft. Ord calls for additional coordination among the three parties to this MOA.

D. The Board of Directors and/or Board of Supervisors of the Monterey County Water Resources Agency has requested changes in the original MOA.

APPENDIX B

AGREEMENTS

1. Consent to project within territory of Ft. Ord. The parties hereto agree that MCWRA may carry out the SIP within the territory presently occupied by Fort Ord and northwards along the coast, may acquire existing wells drawing water from the Salinas Valley and other property within the territory, may provide water to the territory in connection with the SIP, and may exercise any regulatory authority within that territory as may be needed in connection with the SIP and may levy assessments and impose charges in connection with the SIP for water provided within such territory, without any further compliance with the terms of the MOA, notwithstanding that any part of such territory may be located within the boundaries of MPWMD.

2. Future expansion of MPWMD boundaries. If MPWMD boundaries are expanded to include additional territory involved in the SIP, MPWMD will not object to the continued operation of the SIP in that area.

3. Coordination of programs and activities in connection with closure of Fort Ord. The MCWRA, PVWMA, and MPWMD will coordinate programs related to the closure of Fort Ord and will cooperate in the implementation of future developments within the Fort Ord area. In anticipation that a portion of the future water delivery system to the Fort Ord area will be located within the MPWMD area and that the water supply for that system will be developed from the MCWRA area which is outside of the MPWMD area, the MPWMD and the MCWRA will comply with one another's ordinances as follows:

(a) The MCWRA shall have exclusive authority to regulate water delivery systems that deliver water to the area that is both within the present Fort Ord boundaries and within the MPWMD boundaries in existence at the time of the regulation, and the MPWMD will comply with any such ordinance enacted by the MCWRA.

(b) The MPWMD shall have exclusive authority to regulate the management of the Seaside groundwater basin within the present Fort Ord boundaries, and the MCWRA will comply with any such ordinance enacted by the MPWMD.

(c) This Memorandum of Agreement does not commit the MCWRA to provide any specific quantity of water to Fort Ord or to any portion of it, nor does it commit the MCWRA to provide any water to Fort Ord from the Salinas Valley Groundwater Basin. It also does not give to an other agency the authority to compel provision of water to Fort Ord.

4. Deletion of paragraph 18. Paragraph 18 is deleted from the original MOA.

B

5. Deletion of paragraph 19. Paragraph 19 is deleted from the original MOA.

IN WITNESS WHEREOF, the parties execute this memorandum of agreement as follows:

ANNEXATION ASSEMBLY AND EVALUATION REPORT FOR THE ANNEXATION OF FORT ORD BY THE MONTEREY COUNTY WATER RESOURCES AGENCY

10 SEPTEMBER 1993

I. EXECUTIVE SUMMARY. The purpose of this annexation by the Monterey County Water Resources Agency (MCWRA) is to provide the basis for a long term, reliable, potable water supply to support the Army's residual mission at Fort Ord after it is realigned per the Base Closure and Realignment Act of 1990. Annexation will also facilitate the disposal and reuse of the portions of Fort Ord not needed to support the Army's residual mission. This report provides the background and justification for the annexation, which is contingent on the conditions in the accompanying Agreement. See Exhibit 1 for a regional map showing Fort Ord, and Exhibit 2 for the location of cities surrounding Fort Ord.

II. INTRODUCTION.

A. Overview of Annexation.

1. Fort Ord, like all large communities in North Monterey County, obtains all of its water supply from groundwater. From the map at Exhibit 3, it can be seen that the northwestern part of Fort Ord (Area 1) overlies part of the Salinas Valley Groundwater Basin (Salinas Basin). Within Area 1, there are three aquifers known as the 180-foot, 400-foot, and 900-foot aquifers. These aquifers are not necessarily found in every location of Area 1. Presently, Fort Ord has three active potable wells in the 180-foot and 400-foot aquifers of the Salinas Basin (wells 29, 30, and 31). By California law, the MCWRA has water management authority over the Salinas Basin. The Salinas Basin has been in an overdraft condition for many years.

2. The southwestern part of Fort Ord (Area 2 on the map) overlies the Seaside Groundwater Basin (Seaside Basin), which is divided into several subbasins due to geologic conditions. The part of Fort Ord which overlies the Seaside Basin supplies a substantial amount of recharge to this basin. Presently, Fort Ord has only one active well in the Seaside Basin to irrigate the Fort Ord golf courses (well 1). Due to occasional high salinity, water from this well is considered to be non-potable. By California law, the Monterey Peninsula Water Management District (MPWMD) has water Management authority over the Seaside Basin. In contrast to the Salinas Basin, the Seaside Basin appears to be in a nearly balanced condition.

3. In the eastern part of Fort Ord (Area 3 on the map), the boundary between the Salinas and Seaside Basins is not defined. This is not a significant issue since this area has a low

APPENDIX D

infiltration rate and subsurface permeability. As a result, the area is unsuitable for significant groundwater development, and it probably doesn't contribute a substantial amount of recharge to the western basins.

4. Pumping by Fort Ord has contributed to the Salinas Basin overdraft, but only to a limited extent as the Fort Ord withdrawals from 1988 to 1992 averaged only 5,200 acre-feet per year compared to the estimated Salinas Basin overdraft of about 50,000 acre-feet per year. The overdraft has resulted in the intrusion of seawater into the Salinas Basin which has caused the contamination of many wells along the entire coastal region, including several on Fort Ord. Although recent studies show that the rate of seawater intrusion may have slowed in the Fort Ord area, the seawater is continuing at a rapid pace in the Castroville-Salinas area several miles north of Fort Ord. Exhibit 4 shows the seawater intrusion problem. The MCWRA has requested the annexation of all of Fort Ord as part of its long term effort to halt all pumping along the Salinas Basin coastal region by providing a replacement water supply. In this manner, the seawater intrusion could be stopped and perhaps even reversed.

5. Fort Ord realized that the seawater intrusion would eventually contaminate its remaining wells, so in January 1990 the President requested Congress approve a military construction project for $7,400,000 to "Purchase part of a regional water supply system, as the first phase of a two-phase regional water supply project to provide a dependable long-term water supply for Fort Ord and the cities of Marina and Castroville." The fiscal year 1991 Defense legislation provided a $7,400,000 authorization and appropriation for the annexation of Fort Ord into the MCWRA. Additional funds for the Army's share of the regional water supply project (second phase) were never budgeted because the 1991 Defense Base Realignment and Closure process (BRAC 91) dictated that the 7th Light Infantry Division stationed at Fort Ord relocate to Fort Lewis, Washington. As a consequence, the Army deferred action on the annexation until the future status of Fort Ord was determined, and more information was available on the cost for the Army to participate in a regional water supply project.

6. Pursuant to BRAC 91, part of Fort Ord will be retained to support the Defense Language Institute (DLI) at the nearby Presidio of Monterey (POM). This Fort Ord enclave is designated as the POM Annex. Additionally, a 12 acre Reserve Center within Fort Ord will be retained (not contiguous to the POM Annex). As part of the BRAC 93 process, the Army recommended that the POM and POM Annex be closed, and the DLI be relocated to Fort Huachuca, Arizona. However, the 1993 Defense Base Closure and Realignment Commission's recommendations, which the President endorsed to Congress, call for the DLI to remain at the POM, and for the POM Annex to be downsized to only include housing and the commissary, child care facility, and post exchange. Congress is not expected to disapprove the Commission's recommendations.

7. With a BRAC 93 decision to retain an Army presence at Fort Ord, it is imperative that the Army obtain a reliable water supply to support the residual mission. For the Army to gain access to a regional water supply project being developed by the MCWRA, annexation is required. Annexation will also benefit the Army by facilitating the disposal and reuse of the parts of Fort Ord to be excessed. More detail on these and other benefits is provided in section IV.E. of this report.

B. Area to be Annexed. The area to be annexed is the whole of Fort Ord, California, which is made up of 28,602.84 acres. Refer to Exhibits 14 through 18 for real estate maps of the installation.

C. Purpose of the Area and Mission Objectives. Prior to BRAC 91, Fort Ord's primary purpose was to station the 7th Light Infantry Division. Subsequent to BRAC 93, the installation's primary purpose will be to provide housing and other facilities in support of the nearby POM and Naval Post Graduate School.

D. Present and Future Uses of the Property. Relocation of the 7th Light Infantry Division is in progress with the last units scheduled for departure by December 1993. Pursuant to BRAC 91, the Army is disposing of excess property in accordance with applicable law. To support the residual mission, the POM Annex is presently configured to occupy about 1,500 acres. However, under BRAC 93, the POM Annex is to be downsized by excessing facilities such as both golf courses. The Environmental Impact Statement for the disposal and reuse of Fort Ord, which is nearing completion, has identified the following possible uses for the parts of Fort Ord to be excessed: educational, office park (private and government), commercial, recreational, aviation, natural resource management, and housing.

E. Acquisition Origin of Fort Ord. The original Fort Ord reservation comprising 15,809.50 acres was purchased by the United States from the David Jacks Corporation on 4 August 1917. After 1940, an additional 12,793.34 acres were acquired. The total area is 28,602.84 acres.

F. Political Subdivision Seeking Annexation. The subdivision seeking annexation of all the lands comprising Fort Ord is the MCWRA which, per California law, is responsible for managing the surface water and groundwater resources in the Salinas Valley and providing flood control and water conservation services throughout Monterey County. MCWRA is requesting that Fort Ord be annexed into Zones 2 and 2A. The MCWRA established Zone 2 as the benefit assessment zone in connection with the construction of Nacimiento Reservoir (completed in 1957), and established Zone 2A as the benefit assessment zone in connection with the construction of San Antonio Reservoir (completed in 1967). Since the construction of these reservoirs, the MCWRA has operated a groundwater recharge program for the benefit of Zones 2 and 2A, using waters from the two reservoirs and other programs to enhance natural percolation in the Salinas Basin. It is appropriate for Fort Ord to be annexed into Zones 2 and 2A because Fort Ord's potable water supply has historically come from the Salinas Basin. Per a Memorandum of Agreement signed in May 1993 between the MPWMD and MCWRA, the MPWMD does not object to the MCWRA annexing that part of Fort Ord overlying the Seaside basin provided that the MPWMD retains water management authority over the portion of the Seaside Basin underlying Fort Ord. Refer to Exhibit 19 for a large map showing the existing boundaries of Fort Ord and Zones 2 and 2A. Note that although a small portion of Fort Ord is currently shown to be within Zones 2 and 2A, the property is not presently annexed. Refer to Exhibit 20 for a large map showing the entire area of Zones 2 and 2A.

III. LEGAL STATUS OF THE PROPERTY

A. Title Held by the Government. The Army has a fee title interest in the property proposed for annexation. This action by the MCWRA will not affect the Army's title.

B. Degree of Legislative Jurisdiction. The degree of jurisdiction over most of the property is exclusive federal jurisdiction. Annexation will not alter this jurisdiction and it will not interfere with official Army activities or functions including those remaining after realignment and closure.

C. Applicable State Annexation Laws and Ordinances. The procedures for annexation are found in California Water Code, Appendix 52-43 (see Appendix A to the Agreement). The Army intends to petition the MCWRA Board of Supervisors for annexation pursuant to section 43.(b)(3). Pursuant to section 43.(b)(5), annexation may require a fee. See section IV.F. of this report for a discussion of the annexation fee.

D. Regulations on Annexation. The following govern the actions of the Army in annexations:

1. Army Regulation 405-25, Annexation (1 April 1974).

2. Engineering Regulation 405-1-12, Chapter 9, Federal Legislative Jurisdiction and Annexation (Change 4, 5 September 1978).

IV. POTENTIAL IMPACT OF ANNEXATION.

A. Source of Utilities. Water is the only utility that will be affected by the proposed annexation. Fort Ord now receives all of its water from wells on Fort Ord that are owned and operated by the Army. Since seawater intrusion is threatening these wells, the Army needs a long term, reliable, replacement water supply. Such a water supply would likely come from a future MCWRA project; however, the Agreement provides the Army with the flexibility to obtain a replacement water supply from another source if the opportunity arises and it is in the Army's best interests. The replacement water supply system will provide water in bulk to the installation. The Army or a successor entity will continue to be responsible for operating and maintaining the water distribution system on Fort Ord Lands. Paragraph 4.d. of the Agreement addresses the fact that the Army will retain the necessary easements to operate and maintain Army wells.

B. Adverse Impacts on the Mission.

1. Utilities and Services. Annexation will have no impact on Fort Ord utilities and services, or the installation's plan to find a water purveyor to take over the water distribution system.

2. Taxation and Licensing. Municipalities acquire the power to tax private persons and private property by annexation. Military personnel, to some extent, and Government instrumentalities such as Post Exchanges are exempt from such taxation. The Agreement states that the Army will provide the MCWRA with $7,400,000 in consideration for the annexation. However, the Agreement also stipulates that the Army will not pay any MCWRA assessments (including standby charges) until after the POM Annex and Reserve Center gain access to a replacement water supply provided by the MCWRA (see paragraph IV.F.2.). To the extent that federal property may be exempt from local assessments, a utility service contract in accordance with AR 420-41 between the Army and the MCWRA may require the payment of a contractual fee to replace any assessments. Such fee will be mutually agreed upon.

C. Effect on Installation Master Plans. Upon annexation, the MCWRA will acquire some control over Fort Ord's water supply. From a practical standpoint, this control should not prevent the Army from constructing any projects needed to support Fort Ord's residual mission. Additionally, the Agreement provides Fort Ord with special rights to obtain any water needed in the event of war, national emergency, contingency operation, troop mobilization, or unexpected mission requirements.

D. Annexor's Capability to Furnish Benefits.

1. The main benefit the Army expects to receive from the MCWRA is a long term, reliable water supply. Based on its charter, the MCWRA should be the most capable organization to plan, finance, construct, and operate a regional water supply system. The MCWRA's first attempt to develop a water supply system for Fort Ord and Marina was halted in 1992 due to opposition from land owners in and around the proposed Buena Vista well field (located inland from Fort Ord). This project had a capacity of 11,600 acre-feet/year.

2. An alternative project now being studied by the MCWRA consists of dispersed wells along a 20 mile stretch of the Salinas River and storing excess runoff from the Arroyo Seco River (a tributary of the Salinas River) in a shallow aquifer using percolation ponds. Water would then be pumped from the dispersed well system and from the shallow aquifer to replace the potable wells serving Fort Ord, Marina, Salinas, Toro Park, and perhaps other areas in north Monterey County. Water would also be provided to recharge the Salinas Basin near the coast to raise the groundwater level and halt (or even reverse) the seawater intrusion. The Water Transfer Project is being planned for a capacity of about 50,000 acre-feet per year. Construction completion is planned by the year 2000. The MCWRA's current estimated cost of this project is $157 million, which equates to a capital cost of $3,155 per acre-foot per year.

3. There is another MCWRA project to mitigate seawater intrusion which is already under design. The project will upgrade the existing regional sewage treatment plant to tertiary standards, and pipe the effluent to Castroville for crop irrigation. This project should provide about 19,500 acre-feet per year, and is estimated to cost $71 million. When this project comes on line (maybe as early as 1996), the estimated 50,000 acre-feet per year Salinas Basin overdraft will be significantly reduced. This should extend the life of all wells near the coast, including those on Fort Ord. The MCWRA intends to use the Army's $7.4 million annexation fee to complete design of the Castroville Project.

4. Based on the above reasons, it is concluded that the MCWRA is the most capable organization to provide a reliable water supply for the Fort Ord Lands. This is a challenging task as the MCWRA is under considerable pressure to develop a regional water supply project quickly because the wells serving over 100,000 people in the coastal region are being threatened by seawater intrusion. Because of this threat, the State Water Resources Control Board is monitoring the MCWRA's progress in this area. If the MCWRA, for whatever reason, is unable to develop a regional water supply system, then the Agreement permits the Army to obtain a long term water supply for the POM Annex and Reserve Center from another party. Additionally, even if the MCWRA is making progress in developing a regional water supply project, the Agreement provides the Army the option of obtaining a long term water supply for the POM Annex and Reserve Center from another party if it is in the Army's best interests, e.g., the other water source is less costly or available at a more advantageous time.

E. <u>Benefits to Accrue from Annexation.</u> Upon annexation of Fort Ord into Zones 2 and 2A, the MCWRA will not immediately provide any direct governmental service on the installation. The benefits of annexation will accrue initially on an indirect basis, and direct services will be provided later. The benefits to the Army from annexation are as follows:

1. The most important benefit of annexation is that it will allow the Fort Ord Lands to gain access to a regional water supply project being developed by the MCWRA. Fort Ord's existing wells are being threatened by seawater intrusion due to the existing Salinas Basin overdraft. The MCWRA is the most capable, and most likely entity to implement a regional water supply project to support the POM Annex and Reserve Center.

2. Another important benefit is that annexation will facilitate the disposal and reuse of the parts of Fort Ord to be excessed under base closure and realignment. This is the main reason for annexing all Fort Ord Lands at this time instead of waiting to annex just the POM Annex and Reserve Center after the MCWRA has better defined its proposed regional water supply project, i.e., all environmental permits and approvals obtained. Under the Agreement, the new owners of Fort Ord excessed property would have the right to drill and pump on their property subject to the conditions described in paragraph IV.E.3. below, and paragraph 4.c. of the Agreement. Also, property which has already been annexed by the MCWRA will be easier to dispose because of its potential access to a long term water supply project being developed by the MCWRA, and a short term water supply from Fort Ord's existing wells (see paragraph IV.E.3. below). Without annexation, the MCWRA or state regulatory agencies could object to the Army providing water to owners of excessed Fort Ord property, even if only for a short duration. Additionally, these same agencies could severely limit or control pumping by the owners of excessed Fort Ord property due to the Salinas Basin overdraft. Lastly, even if all of these new property owners wanted to be annexed, it would be an administrative burden for the MCWRA compared to annexing just Fort Ord.

3. Until the MCWRA's regional water supply project is implemented, annexation will give the Army the right to withdraw up to 6,600 acre-feet per year from the Salinas Basin underlying Fort Ord Lands, and allow the Army to allocate some of this water for reuse. The Army or its successor water purveyor, utility, or agency may also develop groundwater supplies located outside the Salinas Basin. The amount of water needed to support the Fort Ord residual mission was the subject of a June 1993 Report titled "Water Requirements at Fort Ord Under Base Realignment and Closure", which was prepared under the supervision of the Army Corps of Engineers, Institute for Water Resources (IWR). This report concluded that the POM Annex, as presently configured, would require in fiscal year 1995 1,085 acre-feet of potable water provided that additional water conservation measures are implemented. This report also estimated that 403 acre-feet of non-potable water would be used in fiscal year 1995. The non-potable water is pumped for the golf courses from a well located in the Seaside Basin. These requirements would decrease if the POM Annex is downsized in accordance with BRAC 93. Based on a POM Annex potable water requirement of 1,429 acre-feet per year (IWR estimate plus appropriate adjustments computed by Fort Ord), there could be

up to 5,171 acre-feet per year of water available for reuse and to maintain any undisposed Fort Ord Lands and facilities in a caretaker status. Note that the Agreement only allows 5,200 of the 6,600 acre-feet per year threshold to be pumped from the 180-foot and 400-foot aquifers in the Salinas Basin. Fort Ord's active potable wells draw from the 180-foot aquifer, so a new well into the 900-foot aquifer would be needed to gain access to the additional 1,400 acre-feet per year. The Agreement also states that Fort Ord groundwater withdrawals for environmental restoration will not count toward the 6,600 acre-feet per year threshold because either the withdrawals will be small, or if they are large, the water will probably be disposed in the sanitary sewer system where it will be used by the Castroville Sewage Reclamation/Irrigation Project to help reduce seawater intrusion.

4. There is concern that the Fort Ord wells could become contaminated with seawater before the MCWRA implements their regional water supply project. In this event, annexation would be a benefit to the Army because the MCWRA will provide Fort Ord with the same services as they would provide to any other municipal water supplier in the Zones under this circumstance, i.e., assistance in finding an interim water supply and in obtaining any permits. The Army would bear the cost of obtaining this interim water supply. Under the Agreement, the MCWRA will periodically provide Fort Ord with the estimated remaining life of their wells, and the progress on the MCWRA Water Transfer Project.

5. Annexation will resolve questions concerning Fort Ord's right to withdraw groundwater from the Salinas Basin. The Agreement states that in consideration of the $7,400,000 annexation fee, the MCWRA will release the Government from any financial responsibility for existing MCWRA water projects from which Fort Ord may have benefitted (Nacimiento and San Antonio Reservoirs). Additionally, the Agreement states the MCWRA will release the Government from any claims related to seawater intrusion in the Salinas basin.

6. Under California law, annexation will provide the Fort Ord with the same representation in MCWRA matters as any other property owner in Zones 2 and 2A.

7. Another benefit of annexation is that the enclosed Agreement includes some of the conditions which must be satisfied for the Army to participate in a future MCWRA regional water supply project. The objective of these conditions is to assure that the regional water project costs assigned to the Army are equitable in comparison to the Army's allocation of water from the project. These protections are very important in view of the fact that the Army believed it was being saddled with a disproportionate cost share of the original Buena Vista project, and the fact that the POM Annex will only require a small part of the capacity of MCWRA's proposed regional water project. The Army strongly believes that part of the cost of a regional water project must be funded by all

members of Zones 2 and 2A. The water supply project is just as important to halting seawater intrusion as the Castroville Sewage Reclamation and Irrigation project, and the MCWRA plans to have 50 percent of this project funded by Zone 2 and 2A members not receiving water from the Castroville project.

F. Effect on the Budget of the Installation.

1. Annexation Fee: The Army and the MCWRA have agreed upon an annexation fee of $7,400,000, which was authorized and appropriated by Congress in the fiscal year 1991 Defense legislation. The amount of the fee is related to the benefits provided by MCWRA's existing water projects (Nacimiento and San Antonio Dams) and water management practices which protect the yield of the Salinas Basin. It is from this basin that Fort Ord has historically obtained its potable water supply. The annexation fee is consistent with the current MCWRA Annexation Policy at Exhibit 5. There are two components of the fee - for area and water use. The area component is the area to be annexed in acres times $277. The $277 is the sum of the present worth capital cost of each dam divided by the acreage of its respective zone. The water use component is $783 times the maximum amount of water to be pumped from the Salinas Basin in acre-feet per year. The $783 is the present worth, on a acre-foot per year basis, of past operation and maintenance costs for Zones 2 and 2A. Based on information from current and former Fort Ord personnel, it appears that MCWRA's current annexation policy was in effect when the Congressional budget estimate for the annexation fee was developed in 1989. The area component of the fee was apparently computed by using 8,000 acres multiplied by $277/acre or $2,216,000. Since the existing Fort Ord developed area is about 5,000 acres, the 8,000 acre figure was apparently used to account for future growth. The water use component apparently was developed using the peak withdrawal of 6,600 acre-feet/year (1984) multiplied by $783/acre-foot/year or $5,167,000. The area and water use components total $7,383,800, which was rounded to $7,400,000. The Agreement stipulates that the $7,400,000 fee will be paid to the MCWRA after completeion of the annexation.

2. Annual Assessments: The Agreement stipulates that until the POM Annex and Reserve Center receive water from a MCWRA water supply project, the Army shall not pay any assessments such as standby charges, water delivery charges, or water project assessments. Standby charges, which generally fund the MCWRA administrative costs, vary from year to year and have increased over time. At present, these charges are limited to a maximum of $15 per acre per year for each zone, per the California Water Code, Appendix 52-12. For the POM Annex and the Reserve Center, which after annexation will be in two zones (2 and 2A), this would amount to a maximum of $30 per acre. The Army's potential water project assessments (capital costs) and water delivery charges (operation and maintenance) are discussed in Agreement paragraphs 4.j.(3) and

4.j.(4), respectively. The Agreement stipulates that the Army will not pay any assessments or charges on Fort Ord property in a caretaker status awaiting disposal. Additionally, paragraph 7 of the Agreement provides the MCWRA with expanded authority to collect assessments from Fort Ord property leased to private interests by the Army.

V. POSITION OF COUNTY AND OTHER GOVERNMENT ENTITIES ON ANNEXATION.

A. MCWRA. The MCWRA initiated the annexation of Fort Ord to help solve the Salinas Basin seawater intrusion problem, and guarantee a continuing supply of potable water for Fort Ord. Annexation is a necessary step in this process. The MCWRA is moving toward annexing all property within the Salinas Basin so they can effectively manage the aquifer. With the annexation of Fort Ord and Marina, which are both in progress, all major properties within the Salinas Basin will be annexed.

B. Other Political Subdivisions. Letters were sent by the MCWRA to other communities and agencies that share boundaries with Fort Ord or have an interest in the annexation of Fort Ord by the MCWRA. The respondents, with their comments, are listed below. A sample copy of the letter is attached (Exhibit 6), as well as copies of the responses.

1. City of Monterey, CA; voted not to oppose annexation (Exhibit 7).

2. Monterey County Local Agency Formation Commission; voted to support (Exhibit 8).

3. Marina Coast Water District (formerly known as the Marina County Water District); voted not to oppose annexation (Exhibit 9). The Marina Coast Water District is currently working with the MCWRA to be annexed into zones 2 and 2A because of their concerns over the long term reliability of their existing groundwater supply.

4. Monterey Peninsula Water Management District; approved the annexation (Exhibit 10).

5. City of Del Rey Oaks, CA; voted not to oppose annexation (Exhibit 11).

6. City of Marina, CA; initially voted to table consideration of support or opposition to the annexation. The City of Marina has subsequently agreed not to oppose annexation provided that the Agreement stipulates that Fort Ord may pump up to 6,600 acre-feet of water per year from its wells, and that water not needed for the residual mission can be provided for reuse (Exhibit 12). This provision is contained in paragraph 4.c. of the Agreement.

7. City of Seaside, CA; opposes the annexation (Exhibit 13). It is concluded that in spite of this opposing response, Fort Ord should be annexed by the MCWRA. The first reason is that annexation under the terms of the attached Agreement is in the Army's best interest. The second reason is that the Army concludes there is no reasonable basis for a conflict because the Seaside groundwater supply, which is managed by the MPWMD, will not be affected by the MCWRA's annexation of Fort Ord.

VI. CONCLUSION AND RECOMMENDATIONS. This annexation is in the best interests of the Government, and it is recommended that it be approved contingent on the provisions in the attached Agreement.

REPORT TO THE BOARD OF SUPERVISORS OF THE
MONTEREY COUNTY WATER RESOURCES AGENCY

COPY

SUBJECT	BOARD MEETING DATE	AGENDA NUMBER
APPROVE AND AUTHORIZE THE CHAIR TO SIGN THE AGREEMENT AND ANNEXATION RESOLUTION OUTLINING THE TERMS AND CONDITIONS TO ANNEX FORT ORD INTO MONTEREY COUNTY WATER RESOURCES AGENCY ZONES 2 AND 2A	9-21-93 10:50 AM	
WATER RESOURCES AGENCY		

RECOMMENDATION

Approve and authorize the Chair to sign the Agreement and Annexation Resolution outlining the terms and conditions to annex Fort Ord into Monterey County Water Resource Agency Zones 2 and 2A.

SUMMARY

The United States Army has presented the Monterey County Water Resources Agency (MCWRA) with a petition to be annexed into MCWRA's Zones 2 and 2A. The petition includes an Agreement covering the terms and conditions for the annexation (copy attached). On September 13, 1993 the MCWRA Board of Directors received the Agreement and voted to recommend it be approved by your Board. Since the Agreement has been signed by the authorized representative for the Army, your Board's approval and signature by your Board Chair on the Agreement and Annexation Resolution will complete the annexation action and obligate the Army to a payment of $7.4 million to the MCWRA.

DISCUSSION

On July 10, 1990 the Monterey County Board of Supervisors, acting then for the Monterey County Flood Control and Water Conservation District, authorized the Chair of the Board of Supervisors to sign a Memorandum of Agreement (MOA) that contained the terms and conditions for the annexation of Fort Ord into MCWRA Zones 2 and 2A. The MOA was never co-signed by the Army at that time because it did not address the closure of Fort Ord.

On April, 1993 Army officials on Fort Ord submitted an MOA to the MCWRA for approval. This MOA was approved by the Board of Supervisors on April 20, 1993. When this version of the MOA was received by Army officials in Washington DC, it was rejected on the grounds that it did not sufficiently address the down-sizing of Fort Ord or the Installation's future reuse.

The MOA was changed to an "Agreement" and re-written by Army officials in the Pentagon. The Agreement as is now being presented preserves the key components of the earlier MOA and more completely addresses the Army's declining presence on Fort Ord. It establishes a total cap on groundwater pumping from the Salinas Groundwater Basin, quantifies the amount of water the Army will need for their residual presence and quantifies the amount of water that will be available for civilian reuse.

Approval of the Agreement and the Annexation Resolution by the Board of Supervisors at this time will complete the annexation. The Army will become contractually obligated to pay the agreed annexation fee of $7,400,000 upon being presented with the signed Agreement and Annexation Resolution.

The Agreement consists of the Petition for Annexation and Appendices A, B, C, and D. Exhibits to Appendix D, are available upon request at the offices of the MCWRA.

OTHER AGENCY INVOLVEMENT

In August of 1992 the MCWRA sent a letter to all the Communities surrounding Fort Ord and to other agencies that might be affected by the annexation of the Fort into MCWRA Zones 2 and 2A. The letter indicated the MCWRA's intent to pursue the annexation and it asked the addressees to indicate their support or opposition to the intended action. A summary of the responses is shown on pages 10 and 11 of Appendix D, the Annexation Assembly and Evaluation Report. In addition, on September 9, 1993 the Fort Ord Reuse Group wrote a letter to the Army in support of the annexation.

FINANCING

There is no impact to the General Fund. After annexation, the MCWRA would receive $7.4 million from FY 1991 Military Construction Army appropriated funds. The full amount is scheduled to be applied against the costs of the Castroville Reclamation and Irrigation Project.

Agreement No. A-06404 --
Agreement Between the United States of America and the Monterey County Water Resources Agency Concerning Annexation of Fort Ord Into Zones 2 and 2A of the Monterey County Water Resources Agency, Approved; Chairwoman Authorized to Sign . . . .

Upon motion of Supervisor Johnsen, seconded by Supervisor Strasser Kauffman, and carried, the Board hereby approves Agreement No. A-06404 between the United States of America and the Monterey County Water Resources Agency concerning annexation of Fort Ord into Zones 2 and 2A of the Monterey County Water Resources Agency, and authorizes the Chairwoman to sign said agreement.

PASSED AND ADOPTED this 21st day of September, 1993, by the following vote, to-wit:

AYES: Supervisors Salinas, Shipnuck, Perkins, Johnsen and Karas.

NOES: None.

ABSENT: None.

I, ERNEST K. MORISHITA, Clerk of the Board of Supervisors of the County of Monterey, State of California, hereby certify that the foregoing is a true copy of an original order of said Board of Supervisors duly made and entered in the minutes thereof at page -- of Minute Book 67, on September 21, 1993
Dated: September 21, 1993

ERNEST K. MORISHITA, Clerk of the Board
of Supervisors, County of Monterey,
State of California.

By Nancy Lukenbill
Deputy

Before the Board of Supervisors in and for the County of Monterey, State of California

Resolution No. 93-387 --
A Resolution of the Board of Supervisors of the Monterey County Water Resources Agency Making findings for the Annexation of Certain Territory, Known as the Ft. Ord Annexation, to Zones 2 and 2A of the Monterey County Water Resources Agency, Setting Forth the Conditions for Said Annexation, and Approving Said Annexation.

WHEREAS,

A. For many years, the territory known as Ft. Ord, in Monterey County, California, has obtained its potable water from the Salinas Valley Groundwater Basin.

B. Much of the water in the Salinas Valley Groundwater Basin is derived from the Groundwater recharge program made possible through the operation of Lake Nacimiento and Lake San Antonio. The dams that impound these lakes were built and are operated by the Monterey County Water Resources Agency (MCWRA). The capital, operating and maintenance expenses of these reservoirs have been paid for by the property owners in MCWRA Zones 2 and 2A.

C. Ft. Ord is not in Zones 2 and 2A, and has never paid any of the assessments for the reservoirs, although it has benefited from the groundwater recharge program maintained by Zones 2 and 2A.

D. Over the years, seawater intrusion has progressively advanced into the northern portions of the Salinas Valley Groundwater Basin, rendering wells useless for potable and agricultural purposes and threatening nearby water supplies. Several wells previously used to supply water to Fort Ord have been lost to seawater intrusion.

E. The MCWRA proposes to develop a seawater intrusion program that would replace groundwater wells in the northern portion of the Salinas Valley. The program would rely on groundwater or surface water developed in Zones 2 and 2A. The program would require that all properties to be benefited by the program be in Zones 2 and 2A.

F. The territory of Fort Ord is not in Zone 2 and 2A. The U. S. Government, as owner of said property, desires that the territory of Fort Ord be annexed to Zones 2 and 2A, in order to compensate Zones 2 and 2A for past benefits received and to insure the territory's right to participate in the seawater intrusion program, should a water project be built in Zones 2 and 2A for the benefit of this area.

G. The proposed annexation is not a project within the meaning of CEQA because (1) the terms of the annexation limit the use of water on Ft. Ord to present or historical levels of water use, pending the completion of a water supply project for the benefit of this area, and (2) the annexation does not commit the MCWRA or Ft. Ord to the development of any particular water project or to any other action that will result in changes in the environment. Therefore, it can be seen with certainty that there is no possibility that the annexation will result in significant environmental effects.

H. This annexation is conducted pursuant to the Monterey County Water Resources Agency Act, Section 43.

NOW, THEREFORE BE IT RESOLVED:

1. It is in the best interest of Zones 2 and 2A and the territory described in Exhibit A, referred to herein as the Ft. Ord annexation, that the territory described in Exhibit A be annexed to the zones.

2. The boundaries of the territory to be annexed, as set forth in Exhibit A, are appropriate and need not be modified.

3. There are no other annexation petitions pending before the Agency that involve annexation of any of the same territory to the same zones.

4. The territory described in Exhibit A is hereby annexed to Monterey County Water Resources Agency Zones 2 and 2A, subject to the conditions set forth in the annexation agreement, attached hereto as Exhibit B. The annexation fee shall be paid as provided in Exhibit B.

5. The annexation shall take effect immediately upon the adoption of this resolution.

6. On the effective date of the annexation, the territory described in Exhibit A shall be subject to all the liabilities and entitled to all the benefits of the zone, except as otherwise provided in the annexation agreement, attached hereto as Exhibit B.

Upon motion of Supervisor Johnsen, seconded by Supervisor Karas, the foregoing resolution is adopted this 21st day of September, 1993, by the following vote, to-wit:

AYES: Supervisors Salinas, Shipnuck, Perkins, Johnsen and Karas.

NOES: None.

ABSENT: None.

I, ERNEST K. MORISHITA, Clerk of the Board of Supervisors of the County of Monterey, State of California, hereby certify that the foregoing is a true copy of an original order of said Board of Supervisors duly made and entered in the minutes thereof at page -- of Minute Book 67, on September 21, 1993

Dated: September 21, 1993

ERNEST K. MORISHITA, Clerk of the Board
of Supervisors, County of Monterey,
State of California.

PETITION FOR ANNEXATION
TO ZONES 2 AND 2A
MONTEREY COUNTY WATER RESOURCE AGENCY
MONTEREY COUNTY, CALIFORNIA

AFFIDAVIT

I, the undersigned, declare under penalty of perjury under the laws of the State of California that the attached Memorandum of Agreement with attachments, when executed by the parties thereto, constitutes a petition for the annexation of the territory of Fort Ord, in Monterey County, California, to Zones 2 and 2A of the Monterey County Water Resource Agency, Monterey County, California, by 100 per cent of the owners of the land described therein, and I am informed and believe that the information contained therein is true and correct.

Annexation Agreement and Groundwater Mitigation Framework for Marina Area Lands

March 1996

ANNEXATION AGREEMENT AND GROUNDWATER MITIGATION FRAMEWORK FOR MARINA AREA LANDS

EXECUTIVE SUMMARY

PURPOSE--Groundwater Planning. This Agreement and Framework provides for annexing lands in the Marina area to MCWRA Zones 2 and 2A, the benefit assessment zones for the Nacimiento and San Antonio reservoirs. The Agreement and Framework establishes a groundwater mitigation framework process for the lands to be annexed, and provides money from the Marina area for Basin management planning.

ANNEXATION TO ZONES 2 AND 2A--MCWD, Armstrong, Lonestar. Annexation proceeds under section 7 of the MCWRA Act for lands within the service area of MCWD, and lands owned by Armstrong and Lonestar. Annexation of the MCWD service area was effective immediately upon approval by the MCWRA Board of Supervisors. The Armstrong Ranch annexation will be effective when LAFCO approves concurrent annexation to MCWD and the City of Marina on conditions satisfactory to Armstrong (including recordation of a final subdivision map). The Lonestar annexation will take effect when the Lonestar Property is annexed to MCWD.

Annexation Fees--more than $3,500,000. Annexation fees are based on $277/acre of land annexed, and $783/af of water to be used. The fee for land on which water is not used is $27.70/acre. The fee for agricultural water is $261/af. Annexation fees total more than $3,500,000, plus interest, as follows:

Fees for MCWD are $2,449,410, based on 1,750 acres @ $277/ac. and 3,020 afy of water @ $783/af, and a credit of $400,000 already paid by MCWD for groundwater management planning.

Fees for Armstrong will be about $970,000 for Area A (urban), based on 900 acres @ $277/ac. and 900 afy @ $783/af, and an amount subject to final determination upon actual annexation for Area B (irrigated and unirrigated agriculture). If the annexation of the Armstrong Ranch occurs more than seven years after MCWRA approves the Annexation Agreement, Armstrong will pay the then-current annexation fees. If the agricultural water use on Area B of the Armstrong Ranch changes, Armstrong will pay an additional 2/3 of the then-current water charge portion of the annexation fee, and if water is used on any area annexed as unirrigated, Armstrong will pay an additional 9/10 of the then current land charge.

Fees for Lonestar will be $166,621, based on 104 acres using water @ $277/ac., and 264 acres of unirrigated, vacant land @ $27.70/ac., and 500 afy of water with quality below agricultural standards @ $261/af. If Lonestar's use changes to a potable use, or if Lonestar is supplied water from the MCWD or has water available from the BMP, or if Lonestar uses water on the open-space area, Lonestar will pay the other two-thirds of the water charge.

Payments for MCWD, Armstrong and Lonestar may be in a lump sum, or in installments over 10 years from the date of annexation, with 6% annual interest.

Annexation fees will be dedicated to paying costs of a BMP process that includes benefits for the Marina Area, and for management and protection of the deep aquifer.

Annual Assessments. After annexation, Marina area lands will pay annual assessments for MCWRA Zones 2, 2A and 2Z.

GROUNDWATER LIMITS--4,440 AFY

Pumping Limits. Under the Agreement and Framework, the present MCWD service area is limited to **3020** afy of potable groundwater. Non-agricultural use of Basin groundwater on the Armstrong Ranch is limited to **920** afy, 20 afy when the Agreement and Framework becomes effective, an additional 150 afy upon annexation, and additional increments of 150 afy every two years thereafter. Groundwater underlying approximately 730 acres of the Armstrong Ranch is limited to agricultural use, except that **20** afy can be used for potable uses, and water from that area can also be used at the regional treatment plant. Lonestar will limit its pumping to its current use of **500** afy.

Reclaimed Water Management. MCWD has the right to receive tertiary treated water from the SVRP plant. MCWD will defer taking summer flows of more than 300 afy (all summer flows if a reservoir is built). MCWD will take its entitlement over 300 afy from winter flows, and plan to store the water for use in the summer. MCWD will pay MCWRA for each acre-foot of reclaimed water received from the SVRP, with the price determined each year by a formula.

Water Storage Site. Armstrong will reserve not more than 250 acres of land for the MCWD for a possible water storage site, subject to planning and CEQA compliance. Armstrong will donate the land over about 12 years, as Armstrong's entitlement to potable groundwater use increases in 150 afy increments, or MCWD can acquire land as needed by paying $25,000 per acre (which can be recovered in Armstrong's fees to annex land to MCWD). MCWD, MCWRA, the City of Marina (and MRWPCA, if it signs the Addendum) agree not to take any more land on the Armstrong Ranch, except for specified, limited purposes. Armstrong has reserved well sites to irrigate Area B and to provide water for MRWPCA's regional treatment plant.

Alternate Water Supplies--300 afy of new water.

BMP. MCWRA's BMP planning will include consideration of the Marina area for a Basin alternative to groundwater pumping in the Marina area.

MCWD. MCWD will continue to plan for new water supplies, such as wastewater reclamation and desalination, to replace and supplement groundwater pumping.

Deep Aquifer Management. MCWRA and MCWD will manage the 900' aquifer to protect and preserve it and to sustain a secure water supply source for MCWD.

Water Source for Fort Ord. MCWD's deep wells may be used to provide up to 1400 afy of water already allocated to Fort Ord as part of the Fort Ord annexation to Zones 2 and 2A.

CONSERVATION. MCWD's aggressive water conservation program will continue in the Marina area.

EQUAL TREATMENT. The MCWRA will not impose greater restrictions on the Marina area's water use from the Basin than are imposed on water use or supply for use within the City of Salinas.

MRWPCA ADDENDUM. The Addendum attached to the Agreement and Framework as Exhibit "G" would provide for MRWPCA to join the Agreement and Framework on terms which would include possible acquisition of a buffer zone for the Regional Treatment Plant, and agreement to the other terms of the Agreement and Framework.

ANNEXATION AGREEMENT AND GROUNDWATER MITIGATION FRAMEWORK FOR MARINA AREA LANDS

SUBJECT: **Management and Protection of Salinas River Groundwater Basin; Annexation of Marina Area Lands To Zones 2 and 2A of the Monterey County Water Resources Agency**

1. PURPOSE AND AUTHORITY.

1.1. Purpose. The purpose of this Agreement and Framework is to help reduce seawater intrusion and protect the groundwater resource and preserve the environment of the Salinas River Groundwater Basin through voluntary commitments by the Parties to limit, conserve and manage the use of groundwater from the Salinas River groundwater basin, and to provide the terms and conditions for the annexation of certain territory in the Marina area to the Monterey County Water Resources Agency's benefit assessment Zones 2 and 2A as a financing mechanism providing additional revenues to the Monterey County Water Resources Agency to manage and protect the groundwater resource in the Salinas River Groundwater Basin and to reduce seawater intrusion.

1.2. Authority. This Agreement and Framework is entered into under the authority of the Agency Act, the California Water Code, and the California Government Code.

2. DEFINITIONS AND DESIGNATIONS. The following definitions and designations apply to this Agreement and Framework:

2.1. Parties.

2.1.1. Marina Coast Water District ("MCWD"). A political subdivision of the State of California, located in Monterey County, governed by MCWD's Board of Directors.

2.1.2. Monterey County Water Resources Agency ("MCWRA"). A water and flood control agency created by the State of California, with jurisdiction coextensive with Monterey County, governed by the Monterey County Water Resources Agency Board of Supervisors.

2.1.3. J. G. Armstrong Family Members ("Armstrong"). The owners of the Armstrong Ranch in the Marina area of Monterey County.

2.1.4. RMC Lonestar ("Lonestar"). A California general partnership and owner of the Lonestar property in the Marina area of Monterey County.

2.1.5. City of Marina ("City"). An incorporated municipality within Monterey County, organized and operating under the laws of the State of California, governed by its City Council.

2.2. AFY. Acre-feet per year.

2.3. Agency Act. MCWRA's enabling legislation adopted by Chapter 1159 of the Statutes of 1990, and Chapter 1130 of the Statutes of 1991, set forth in full in West's California Water Code Appendix, Chapter 52.

2.4. Armstrong Ranch. About 1850 acres of land in the Marina area, as shown on Exhibit "C," about 322 acres of which is within the City of Marina, plus an additional 150 acres not shown on Exhibit "C" which is already in the Zones.

2.5. Basin. The Salinas River Groundwater Basin.

2.6. BMP. The MCWRA's Basin Management Plan for the Salinas River Groundwater Basin.

2.7. CEQA. The California Environmental Quality Act, Public Resources Code sections 21000 and following.

2.8. CSIP. The Castroville Seawater Intrusion Project, a distribution system project already approved and being implemented by MCWRA to provide reclaimed water for irrigation in the Castroville Area of Monterey County.

2.9. Effective Date. Subject to paragraph 4, this Agreement and Framework shall be fully effective when executed by all the Parties.

2.10. Exhibits.

"A" The general geographic relationship of MCWD, Armstrong and Lonestar to the Basin and to the Zones is shown on the diagram attached to this Agreement and Framework as Exhibit "A."

"B" MCWD service area to be annexed

"C" Armstrong Ranch land to be annexed

"D" Lonestar property to be annexed

"E" Calculation of Incremental Cost for Tertiary Treated Water

"F" Armstrong Areas Reserved For Transfer to MCWD

"G" MRWPCA Addendum

2.11. FEIR. The Final Environmental Impact Report for the Salinas Valley Seawater Intrusion Program (February 1992).

2.12. Fort Ord. The land within the boundaries of the former Fort Ord Military Reservation.

2.13. Lonestar Property. A parcel containing about 400 acres of land in the Marina area, as shown on Exhibit "D."

2.14. Marina Area. Lands served by, adjacent to, or within the sphere of influence of MCWD.

2.15. MCWD Water Plans. The Urban Water Master Plan and the Urban Water Shortage Contingency Plan adopted by MCWD.

2.16. MCWRA/MRWPCA Agreement. Monterey County Agreement No. A-6078, "Agreement Between The Monterey County Water Resources Agency And The Monterey Regional Water Pollution Control Agency For Construction And Operation Of A Tertiary Treatment System," dated for reference purposes June 16, 1992, as amended on or before December 1, 1995.

2.17. Mitigation Plan. A plan for a potable water supply capable of mitigating the effects of seawater intrusion and providing a long-term potable water supply to MCWD's distribution system.

2.18. Mitigation Plan Implementation. The Mitigation Plan shall be considered "implemented" upon the delivery of potable water to MCWD's distribution system from a completed, long-term, potable water supply system, after system testing has been successfully completed.

2.19. Agreement and Framework. This Annexation Agreement and Groundwater Framework for Marina Area Lands.

2.20. Monterey Regional Water Pollution Control Agency ("MRWPCA"). A joint powers authority providing sewage treatment service to its member entities in Northern Monterey County, governed by its Board of Directors.

2.21. MRWPCA Annexation Agreement. "Annexation Agreement Between The Marina County Water District And The Monterey Regional Water Pollution Control Agency," dated April 25, 1989, as amended on or before December 1, 1995.

2.22. 1990 Agreement. Monterey County Agreement No. A-5471, "Preliminary Agreement Between United States of America, Marina Coast Water District, and Monterey County Flood Control and Water Conservation District," dated July 12, 1990.

2.23. SVRP. The Salinas Valley Reclamation Project, a project already approved and being implemented by MCWRA, in cooperation with MRWPCA, to reclaim water at the MRWPCA's regional treatment plant, for irrigation through the CSIP.

2.24. Zones. Zones 2 and 2A of the MCWRA, which are the zones of benefit and assessment for the MCWRA's Nacimiento and San Antonio reservoirs.

3. FACTS AND CIRCUMSTANCES. This Agreement and Framework is entered into with regard to the following facts and circumstances:

3.1. The MCWRA has approved fourteen other annexations to Zones 2 and 2A since 1991. Like other areas which have been annexed, the Marina area is within the Salinas River Groundwater Basin, has been using groundwater for many years, and has strong claims to groundwater rights. Since the Fort Ord annexation in 1993, the Marina area is surrounded on three sides by Zones 2 and 2A, and by Monterey Bay to the west.

3.2. MCWRA agreed in the 1990 Agreement to "encourage and support" annexing MCWD to Zones 2 and 2A. MCWD has worked for about thirteen years with the MCWRA on plans for a reliable, long-term water supply for the northern Basin area, including the Marina area and Fort Ord. MCWD's participation has included payment of money to assist the planning effort. As part of the 1990 Agreement, MCWD paid for survey and planning work for the long-term water supply effort. Sums paid by MCWD to MCWRA total over $400,000. The work for which MCWD paid will be useful for the Mitigation Plan.

3.3. MCWD, City, Armstrong and Lonestar claim the right to use groundwater from the Basin, to the full extent provided by law. MCWD takes water from wells owned and operated by MCWD and drilled into the "180-foot", "400-foot" and "900-foot" aquifers in the Basin. About ninety-eight percent of potable water used currently by MCWD comes from the 900-foot aquifer. MCWD's current maximum pumping capacity is 5,800 gpm (9,350 afy) of potable water and 1,100 gpm (1,770 afy) of other usable water. Allowing for routine maintenance and providing a contingency factor for emergency shutdown, MCWD's current estimated operational pumping capacity for potable water is 3900 gpm (6,000 afy).

3.4. MCWD agreed in writing in 1988 to cooperate with the City in providing water service to the Lonestar property and the Armstrong Ranch. A coordinated and centralized water supply for the Marina Area in furtherance of that 1988 agreement will facilitate management and protection of the groundwater resource in the Marina Area. Armstrong claims the right and ability to use not less than 920 afy of potable water from the Basin to provide potable water service to the Armstrong Ranch, and the right to use water for agricultural purposes. MCWD currently supplies some water to the Armstrong Ranch. The Armstrong Ranch will need reclaimed water for golf course purposes, park purposes and such other general uses as may be required by any agency having jurisdiction as a condition of development. The Lonestar property currently uses about 500 afy of groundwater from the Basin.

3.5. The MCWD Water Plans are based on a total need within MCWD's current boundaries of 3,020 afy of water for potable uses and about 280 afy additional water suitable for irrigation, and on additional projected need by the rest of the Marina area as specified in the MCWD Water Plans.

3.6. MCWRA has previously annexed Fort Ord into Zones 2 and 2A. The September 1993 Agreement for that annexation provides that until implementation of a project to provide a substitute supply, a maximum of 6,600 afy may be withdrawn from the Basin for use on Fort Ord lands, provided no more than 5,200 afy are withdrawn from the 180-foot aquifer and 400-foot aquifer. The USA received a credit against annexation fees for about $400,000 paid under the 1990 Agreement.

3.7. Pursuant to paragraph 12 of the MRWPCA Annexation Agreement, MCWD has the right to obtain from the MRWPCA, at the regional treatment plant, treated wastewater for reuse by the MCWD in quantities equal to the volume of MCWD wastewater treated by MRWPCA and such additional quantities as from time to time are not committed to any other users for beneficial use. MCWD's cost for such treated wastewater will be the MRWPCA's incremental cost over secondary treatment, to meet applicable local, state and federal requirements for water reuse.

3.8. The MCWRA/MRWPCA Agreement provides that the SVRP shall be designed and built for tertiary treatment of wastewater to be used for irrigation through the CSIP. That Agreement also mentions possible future interties with other agencies. The MCWRA/MRWPCA Agreement commits flows of wastewater to the CSIP as provided in Article IV and Exhibit C of that Agreement, excepting flows taken by MCWD pursuant to the MRWPCA Annexation Agreement.

4. REQUEST FOR ANNEXATION.

4.1. Request by MCWD, Armstrong, and Lonestar. Execution of this Agreement and Framework shall be deemed to be a formal and joint request by the signatories that the MCWRA's Board of Supervisors exercise their authority under section 7 of the Agency Act (West's California Water Code App. § 52-7) to annex to the Zones the lands described in Exhibits "B", "C" and "D" to this Agreement and Framework, on the terms and conditions of this Agreement and Framework as executed by the requesting signatories. No other terms or conditions shall apply to any annexation under this Agreement and Framework without the written agreement of all the Parties affected by the change.

4.2. Request by MCWD. MCWD is requesting immediate annexation of all the lands described in Exhibit "B." The lands to be annexed include the land which contains Olson School and the Methodist Church.

4.3. Request by Armstrong. Armstrong is requesting annexation of its land described in Exhibit "C", which annexation would take effect as provided in paragraph 6.2 of this Agreement and Framework.

4.4. Request by Lonestar. Lonestar is requesting immediate annexation of its land described in Exhibit "D", which annexation would take effect as provided in paragraph 7.3. of this Agreement and Framework.

4.5. Effect of Request. Other than to serve as a formal annexation request pursuant to section 7 of the Agency Act, this Agreement and Framework shall have no effect until its execution by the MCWRA.

5. TERMS AND CONDITIONS--MCWD.

5.1. Quantity limitations on MCWD's groundwater pumping.

5.1.1. Commencing on the effective date of this Agreement and Framework and continuing until Mitigation Plan Implementation, MCWD will limit its withdrawal of potable groundwater from the Basin for land in the Marina area and outside the former Fort Ord Military Reservation to 3,020 afy of potable groundwater, and only such additional quantities as are permitted by this paragraph 5.1. MCWRA's groundwater resource planning for the existing MCWD service area will be based on the latest information and projections contained in the MCWD Water Plans, using 3,020 afy as a planning guideline for potable water use.

5.1.1.1. After compliance with all applicable requirements of law, including but not limited to CEQA, MCWD may improve the interconnection between the MCWD water system and the water system serving Fort Ord, to provide for joint, conjunctive and concurrent use of all system facilities to serve Fort Ord and other areas served by MCWD, and the other Parties will cooperate on MCWD's increased withdrawal of potable groundwater by up to 1,400 afy from the 900-foot aquifer to enable the increased withdrawals from 5200 afy to 6600 afy for use on Fort Ord, as provided in paragraph 4.c. of the September 1993 Agreement between The United States of America and the MCWRA.

5.1.1.2. If the Armstrong property has been annexed to the Zones, the other Parties will cooperate on MCWD's increased withdrawal of up to 920 afy from the Basin, on the condition that such withdrawals shall be used only to provide water to the Armstrong Ranch and, to the extent that such water is requested and accepted by Armstrong, such use shall in its entirety be applied to the satisfaction of Armstrong's entitlement under paragraph 6.9. of this Agreement and Framework.

5.1.1.3. If the Lonestar property has been annexed to the Zones, the other Parties will cooperate on MCWD's increased withdrawal of up to 500 afy from the Basin, on the condition that such withdrawals shall be used only to provide water to the Lonestar property, and, to the extent that such water is requested and accepted by Lonestar, such use shall in its entirety be applied to the satisfaction of Lonestar's entitlement under paragraph 7.2. of this Agreement and Framework.

5.1.2. Conditioned upon MCWRA's compliance with paragraphs 5.1, 5.2, 5.3., 5.5, 5.7, 8.1, 8.2 and 8.3, after Mitigation Plan Implementation, MCWD will be governed by such limitations on the withdrawal of water from the Basin as shall be included in the terms of the Mitigation Plan.

5.2. <u>No objection by MCWRA to MCWD withdrawals except pursuant to section 22 of Agency Act</u>. The MCWRA shall not object to any withdrawal by MCWD which is mentioned in section 5.1 above, except in compliance with section 22 of the Agency Act. All groundwater withdrawn from the Basin by MCWD may be used only within the Basin.

5.3. <u>Management of 900-foot aquifer</u>. The Parties agree that the "900-foot" aquifer should be managed to provide safe, sustained use of the water resource, and to preserve to MCWD the continued availability of water from the "900-foot" aquifer. The Parties will work to include in a Mitigation Plan the concept that water from the Mitigation Plan which costs less than the cost of desalinated water should be the primary source of potable water for the lands described in Exhibits "B", "C", and "D", and wells in the "900-foot" aquifer should be a secondary source, if seawater intrusion is shown to be affecting the "900-foot" aquifer by credible scientific evidence. The Parties will also work together on measures to protect the "900-foot" aquifer.

5.4. <u>Compliance with CEQA and other applicable laws</u>. MCWD's participation in the Mitigation Plan or any other alternative water supply plan is subject to compliance with all applicable laws, including but not limited to CEQA, and to review and approval by the MCWD.

5.5. <u>MCWD development of alternative water supplies</u>. MCWRA agrees that it is appropriate for MCWD to plan for and develop any new water supplies, including but not limited to wastewater reclamation and desalination, that help to meet MCWD's needs, except that the MCWRA believes that the unilateral development of water by MCWD would not be appropriate from any of the following sources: the 180-foot and 400-foot confined aquifers in the Pressure Area of the Salinas Valley Groundwater Basin, the unconfined aquifer in the three other areas in the Salinas Valley Groundwater Basin (East side, Forebay, and Upper Valley), and the Salinas River and its tributaries.

5.6. <u>MCWD payment to MCWRA for tertiary treated water</u>. In satisfaction of paragraph 12 of the MRWPCA Annexation Agreement, MCWD will pay to MCWRA the incremental cost over secondary treatment to receive tertiary treated water from MRWPCA's planned tertiary treatment facilities at its regional treatment plant. The Parties agree that this cost shall be calculated as set forth on Exhibit "E" to this Agreement and Framework.

5.7. MCWD right to receive tertiary treated water from MRWPCA plant.

5.7.1. Pursuant to the MRWPCA Annexation Agreement, on or after the date of first delivery of water from the CSIP and upon compliance with all then-applicable requirements of law, including but not limited to CEQA, MCWD shall have the right to receive tertiary treated water from the tertiary treatment plant constructed and maintained pursuant to the SVRP, as provided herein.

5.7.2. The CSIP requires maximum available reclaimed water flows from the SVRP during the months of April through September to replace historically high uses of groundwater during those months, and to thereby maximize environmental benefits. Accordingly, during the months of April through September, MCWD agrees to defer taking any water over 300 afy it is entitled to take from the tertiary treatment plant under the MRWPCA Annexation Agreement. MCWD will also defer taking the first 300 afy of such flows to which it is entitled, if and after MCWD constructs a reservoir to store replacement winter flows.

5.7.3. During the months of October through March, MCWD may take the full amount of the reclaimed water to which it would, under the MRWPCA Annexation Agreement, have first priority during those months, together with an amount of water equal to the amount deferred during the immediately preceding months of April through September under paragraph 5.7.2. above. MCWD will take the deferred amount in equal or approximately equal monthly portions spread throughout the October-March period, or as otherwise agreed in writing by the MCWD and the MCWRA.

5.7.4. If MCWD's ability to supply reclaimed water is interrupted for any reason, MCWD and MCWRA will act jointly and diligently, together and with MRWPCA, to mitigate possible damage to users of such flows, including possible interim use of MCWD's wells to provide a substitute source of water.

5.8. Effective date of annexation. The annexation to Zones 2 and 2A of the MCWD lands described in Exhibit "B" shall take effect immediately upon approval of the annexation by the MCWRA Board of Supervisors on the terms of this Agreement and Framework, or, if the annexation is approved by ordinance, then thirty (30) days after adoption of an ordinance approving the terms of this Agreement and Framework.

5.9. Annexation fee.

5.9.1. Amount of MCWD annexation fee. To annex all the land described in Exhibit "B" to the Zones, MCWD shall pay to MCWRA an annexation fee in the amount of Two Million Eight Hundred Forty-Nine Thousand Four Hundred and Ten Dollars ($2,849,410.00) (based on 1750 acres in the MCWD service area and water extraction use of 3020 afy). MCWD shall pay this amount, subject to any adjustments hereinafter described, in semi-annual installments as provided in paragraph 5.9.3. below. By giving written notice to MCWRA on or before May 1, 1997, MCWD may elect to pay the annexation fee in full, without interest, in one lump sum on or before July 1, 1997.

5.9.2. Credit. MCWD shall have a credit of $400,000 against the annexation fee, based on the 1990 Agreement and the similar credit previously given to the U.S.A. on the annexation of Fort Ord to the Zones.

5.9.3. Payment of annexation fee. MCWD shall pay its annexation fee as follows:

5.9.3.1. From the total amount of the annexation fee, subtract the credit of $400,000, to determine the "net annexation fee." MCWD may elect to pay the net annexation fee in one lump sum, as provided in paragraph 5.9.1, or may pay in installments as provided below. If MCWD elects to pay in one lump sum, any late payment shall bear interest at the annual rate of 6% from the due date and shall be subject to the same penalties and collections procedures as are set forth in paragraph 6.7. of this Agreement and Framework.

5.9.3.2. MCWD may pay in twenty semi-annual installments, beginning in the fiscal year commencing on July 1, 1997, with interest at the annual rate of six percent (6%) on the unpaid principal balance accruing from July 1, 1997, and with semi-annual payments due on November 1 and February 1 and delinquent on December 10 and April 10 each fiscal year. The interest included in payments consisting of both principal and interest shall be calculated as though the installment were paid on the last day before delinquency, even if the installment is paid in advance of that date. The total amount of each installment paid on the net annexation fee shall be sufficient to amortize the full amount of principal and interest in twenty (20) equal semi-annual installments. There shall be no pre-payment penalty.

5.10. MCWD use of revenues prior to full payment of annexation fee. Until MCWD pays or receives credit for the entire annexation fee and all accrued interest on the fee, all revenue received by MCWD from the lands annexed to the Zones pursuant to this Agreement and Framework for or in connection with providing water and sewer service to the lands shall be used only for activities and functions duly performed by MCWD in connection with providing water and sewer service, including, but not limited to, the payments required under this Agreement and Framework.

6. TERMS AND CONDITIONS--ARMSTRONG.

6.1. Ranch Areas. Annexation of the Armstrong Ranch to the Zones contemplates two general areas of the Ranch, which are designated for convenience "Area A" and "Area B." Area A consists of about 900 acres which is expected to be developed for urban uses. Area B consists of about 950 acres, a portion of which is expected to be used for irrigated agriculture, and about 220 acres of which is expected to be given to MCWD to store treated water. For purposes of determining assessments, standby charges and the like, the initial classification of the land within Area B will be determined at the time of annexation.

6.2. Effective Date of Annexation. Approval of this Agreement and Framework by the MCWRA Board of Supervisors shall constitute approval for annexation of the Armstrong Ranch to the Zones at the time and on conditions approved by LAFCO and satisfactory to Armstrong for concurrent annexation of the Armstrong Ranch to MCWD and the City of Marina, including recordation of a final subdivision map upon conditions satisfactory to Armstrong.

6.3. Participation by Armstrong in MCWD water sources. Subject to compliance with all then-applicable requirements of law, including but not limited to CEQA, Armstrong Ranch shall be entitled at all times to participate on an equitable basis with MCWD in potable water sources developed by MCWD pursuant to paragraph 5.5. of this Agreement and Framework, in which event the limitations concerning the use of water on the Armstrong Ranch, as set forth in paragraph 6.9. shall not be applicable to using potable water developed pursuant to paragraph 5.5.

6.4. Prerequisites to annexation to MCWD and the City of Marina. Any application to LAFCO for annexation of any Armstrong Ranch property to either MCWD or the City of Marina shall be concurrently submitted by the City and MCWD, and shall provide that such property to be annexed shall be within the boundaries of both MCWD and the City of Marina.

6.5. Annexation fee.

6.5.1. When the Armstrong Ranch has been annexed to the Zones, Armstrong will pay to MCWRA an annexation fee computed as the sum of

6.5.1.1. the product of multiplying the number of acres annexed by $277/acre for land intended for urban or irrigated use and $27.70/acre for land intended for grazing, dry land farming or other unirrigated use, and

6.5.1.2. the product of multiplying the number of afy of water from the Basin or the Mitigation Plan allocated to the annexed land by $783/af for potable water intended for urban use and $261/af for water intended for agricultural use. Such charge shall not be applicable to any water from a source other than the Salinas Valley Groundwater Basin or the Salinas River and its tributaries.

6.5.2. Fees for Armstrong are estimated to be about $969,660 for Area A, based on 900 acres @ $277/ac. and 920 afy @ $783/af, and an amount subject to final determination upon actual annexation for Area B. For example, based on 250 irrigated acres @ $277/ac., 700 unirrigated acres @ $27.70/ac., and 650 afy of water @ $261/af, the annexation fees for Area B would be about $258,000.

6.5.3. If annexation of the Armstrong Ranch occurs more than seven years after MCWRA approves this Agreement and Framework, Armstrong shall pay the then-current annexation fees, instead of the fees set forth in paragraph 6.5.1 above.

6.5.4. Armstrong may elect to pay the annexation fee in a lump sum as provided in paragraph 6.6 below, or may pay the annexation fee in installments as provided in paragraph 6.7 below. There shall be no prepayment penalty.

6.5.5. If the agricultural water use on Area B is changed to a potable or industrial use, then Armstrong shall pay to the MCWRA as an additional annexation fee, an additional water charge computed as two-thirds (2/3rds) of the product of the number of afy changed multiplied by the then-current annexation water charge. If Armstrong uses water on any part of the Armstrong Ranch which is initially annexed as land for unirrigated use, Armstrong shall pay an additional land fee of nine times the land fee specified for such land in 6.5.1.1 above. The additional water charge or land fee will be paid either in one lump sum, due and payable on the July 1 immediately following the change in water use, or in twenty (20) equal semi-annual installments over ten (10) years, with the payment period and interest accrual beginning on that July 1, in the same manner as prescribed for Armstrong's original annexation fee and subject to the same rules.

6.6. Payment of annexation fee in lump sum. If paid in a lump sum, the annexation fee shall be due and payable in full on July 1, next succeeding the first March 1 after the effective date of the annexation. Armstrong may elect to pay the annexation fee in full in one lump sum by giving written notice of such election to MCWRA not later than the May 1 immediately preceding the date payment is due. Any late payment shall bear interest at the annual rate of 6% from the due date, and shall be subject to the same penalties and collection procedures as are set forth in paragraph 6.7.

6.7. <u>Payment of annexation fee in installments</u>.

6.7.1. If paid in installments, the installments shall include interest on the unpaid principal balance at the annual rate determined in the manner hereinafter set forth, which interest shall begin to accrue on July 1, next succeeding the first March 1 after the effective date of the annexation. The interest rate on installments shall be six percent per annum. The interest included in each installment shall be calculated as though the installment were paid on the last day before delinquency, even if the installment is paid in advance of that date.

6.7.2. The amount of each semi-annual installment shall be sufficient to amortize the full amount of principal and interest in twenty (20) equal semi-annual installments.

6.7.3. The semi-annual installments shall be paid and collected at the same time and in the same manner and by the same persons as, and together with and not separately from, general agency and zone taxes and shall be delinquent at the same time and thereafter subject to the same delinquency penalties. The first installment shall be due on November 1 following July 1, next succeeding the first March 1 after the effective date of the annexation and shall be delinquent if not paid on or before the following December 10. The second installment shall be due on the following February 1 and shall be delinquent if not paid on or before the following April 10. Thereafter, installments shall fall due and become delinquent on the same dates each year.

6.7.4. The full amount of principal and interest shall be paid not later than April 10, in the tenth year following July 1, next succeeding the first March 1 after the effective date of the annexation.

6.7.5. The amount of each installment shall constitute a lien on each annexed parcel as of noon on the March 1 immediately preceding the fiscal year (July 1-June 30) in which payment of the installment will be due. If the property is subdivided, then a prorata share of the annexation fee shall become a lien on each individual parcel, based upon the ratio that the land area of the individual parcel bears to the total land area of all parcels against which the annexation fee is a lien. All laws applicable to the levy, collection and enforcement of general agency and zone taxes, including, but not limited to, those pertaining to delinquency, correction, cancellation, refund and redemption, shall be applicable to such installments.

6.7.6. MCWD shall pay to MCWRA any fees to annex the lands within the MCWD Reserved Area described in paragraph 6.10 and shown on Exhibit "F" to this Agreement and Framework.

6.8. <u>Costs, assessments, fees and charges</u>. Costs, assessments, fees and charges imposed by MCWD in connection with providing water and wastewater treatment capacity and service to the Armstrong Ranch must be equitable and reasonable and must be reasonably related to services and benefits received, consistent with the County Water District Law (Water Code sections 30,000 and following), with Government Code sections 50076 and 66013, and with applicable case law.

6.9. Quantity limitations on Armstrong water use.

6.9.1. Armstrong shall have the right to utilize on the Armstrong Ranch groundwater for irrigation, and 920 afy of additional water for potable uses withdrawn from the Basin, subject to the limitations set forth herein. Armstrong shall limit potable water withdrawn from the Basin and used for potable purposes on the Armstrong Ranch to no more than 20 afy when this Agreement and Framework becomes effective, 150 afy upon annexation to the Zones, and an additional 150 afy every two years thereafter, up to the total of 920 afy for potable purposes from the Basin.

6.9.2. MCWD shall provide Armstrong with water service for all residential, municipal and industrial uses on the Armstrong Ranch. In providing such service, the water allocation for Armstrong, set forth above in paragraph 6.9.1., shall be added to the MCWD water allocation, as provided in paragraph 5.1.

6.9.3. Groundwater underlying Area B shall be used solely for agricultural activities conducted on Area B, except that not more than 20 afy of such groundwater may be used for potable uses on the Armstrong Ranch, and additional groundwater underlying Area B also may be used by the MCWD on the part of Area B conveyed to MCWD and may also be used on the adjacent lands of the MRWPCA.

6.9.4. The limits on water use provided by this paragraph 6.9. shall not apply to use of reclaimed water or of potable water developed from a source other than the Salinas Valley Groundwater Basin or the Salinas River and its tributaries.

6.10. Reservation of lands for MCWD.

6.10.1. MCWD Reserved Area . Armstrong shall reserve, for use by MCWD, the area shown diagrammatically on Exhibit "F" to this Agreement and Framework as "MCWD Reserved Area", and the non-exclusive easements shown on Exhibits "C" and "F" in favor of MCWD, appurtenant to said MCWD Reserved Area and to MCWD's reclaimed water system and transferrable with either, for construction, roads, utilities (including communications), pipelines, and any other purpose for which a road may be used, subject to the non-exclusive easements shown on Exhibits "C" and "F" to be reserved in favor of Armstrong, which said reserved easements in favor of Armstrong shall be for wells (located within the southerly 60' of the 160' x 1000' strip as shown on Exhibit "F", which wells may be relocated within said strip from time to time, on well sites which may extend north of the southerly 60' of the strip) for agricultural irrigation, roads, utilities (including communications), pipelines, and any other purpose for which a road may be used, shall be freely assignable and usable by others, and not subject to being extinguished or limited because of overburden or surcharge, and which said reserved easements shall not interfere or be used so as to interfere with the use of the balance of said MCWD Reserved Area for the production, storage, or distribution of treated water (tertiary treatment or its equivalent), or potable water. Before either MCWD or Armstrong installs any facilities in the reserved easements, MCWD and Armstrong will meet and confer to assure that their respective uses of and facilities in the said reserved easements will not conflict. Both parties shall act reasonably in considering the needs of the other. MCWD shall not place any non-potable water impoundment within the 160′ x 1000′ strip, nor any non-potable water pipeline closer than 110′ north of the southerly boundary. MCWD shall not be required to move any facilities the installation of which has been approved by Armstrong. Water from wells located in said reserved strip shall be used only on lands of Armstrong and also may be used by the MCWD on the part of Area B conveyed to MCWD and may also be used on the adjacent lands of the MRWPCA.

6.10.1.1. The MCWD Reserved Area, which shall not exceed 250 acres within the boundaries shown on Exhibit "F", will be "office" surveyed at the expense of MCWD within sixty days, and "field" surveyed at the expense of MCWD within one year, following approval by the MCWRA Board of Supervisors of this Agreement and Framework.

6.10.1.2. MCWD will diligently undertake, and MCWRA, City and Armstrong will cooperate in the planning and conduct of, the appropriate environmental review and application for appropriate permits to use MCWD Reserved Area for facilities for the production, storage, or distribution of treated water (tertiary treatment or its equivalent), or potable water. Any use other than for the production, storage, or distribution of treated water (tertiary treatment or its equivalent), or potable water, shall require the prior written approval of Armstrong, and any conveyances from Armstrong to MCWD shall contain appropriate restrictions on such additional use in the form of a condition subsequent to the conveyances and a power of termination in favor of Armstrong. Any attempt to condemn the power of termination shall be subject to the provisions of paragraph 6.10.3. as if it were a condemnation of fee title.

6.10.1.3. MCWD may use and take conveyance of the MCWD Reserved Area in phases of not less than 40 acres. Armstrong's obligation to reserve the MCWD Reserved Area shall expire at midnight on June 30, 2003, or upon delivery to Armstrong of written notice from MCWD cancelling MCWD's right to receive conveyance of the MCWD Reserved Area. Armstrong's obligation to reserve the MCWD Reserved Area shall be extended to July 1, 2010, if MCWD has begun to use at least 40 acres of the MCWD Reserved Area by June 30, 2003.

6.10.2. Gift by Armstrong or payment by MCWD. Armstrong has offered to make a gift to MCWD, at the agreed value of $25,000 per acre, of 50 acres of the MCWD Reserved Area for the first 150 afy of water which Armstrong is entitled to withdraw from the Basin as provided in paragraph 6.9. of this Agreement and Framework, and 40 acres for each additional 150 afy which Armstrong may withdraw pursuant to paragraph 6.9, or less than 40 acres for the last 150 afy, if the last remaining portion of the MCWD Reserved Area is less than 40 acres, but in no event to exceed the total acreage of the area shown as the MCWD Reserved Area on Exhibit "F" to this Agreement and Framework. This offer may be accepted by MCWD following such final annexation at any time during the time Armstrong is reserving the MCWD Reserved Area. In any event, however, and notwithstanding the foregoing, upon receipt by Armstrong of written request from MCWD, Armstrong will forthwith convey all or part of the MCWD Reserved Area to MCWD by grant deed. Any such part must begin in the southwest corner of MCWD Reserved Area, must be parallel to the southerly and westerly boundaries of the MCWD Reserved Area, must be rectangular or trapezoidal in shape, must be at least 40 acres in size, and must be free of any financial encumbrances except taxes and assessments not delinquent, but subject to all other encumbrances, and further subject to all laws, ordinances, regulations and rights of all governmental bodies having jurisdiction in, on or over the subject real property as they may from time to time exist. Title shall also be subject to the lien of a first deed of trust for each conveyance, executed by MCWD in favor of Armstrong securing the obligation of MCWD in favor of Armstrong next hereinafter referred to. Beginning six months after conveyance of any part of the MCWD Reserved Area which is not conveyed as a gift to MCWD, MCWD shall commence paying to Armstrong a sum calculated by multiplying the number of acres in such conveyance by Twenty-Five Thousand Dollars ($25,000.00). The price of $25,000 per acre shall be adjusted as of July 1, 2003, if Armstrong's obligation to reserve the property is extended to 2010 pursuant to paragraph 6.10.1.3. of this Agreement and Framework. In such event, the price per acre shall be computed by multiplying $25,000 by the percentage increase or decrease in the Cost of Living Index for all urban consumers in the San Francisco-Oakland-San Jose Area (1982-1984=100), occurring between July 1, 1997 and July 1, 2003, or the closest dates to such dates for which figures are available. Payment shall be made in 20 equal semi-annual payments, commencing six months after such conveyance, sufficient to amortize the obligation fully, with the unpaid principal balance bearing interest from the date of conveyance to MCWD, at the prime rate of the Bank of America in San Francisco, California, as of July 1 each year during the term of this obligation, but not to exceed the maximum rate permitted by law to be charged by Armstrong in such transaction. Any such payments made or to be made by MCWD, together with interest from the date of MCWD's payment, through December 31, 2010, at the prime rate of interest of the Bank of America in San Francisco, California, shall be included in computing annexation fees, capacity charges and service charges charged by MCWD for the part of the Armstrong Ranch to which the payments made by MCWD to Armstrong relate.

6.10.3. Waiver of further acquisitions by MCWD, MCWRA, and City of Marina; liquidated damages. Except for incidental water system and wastewater system and storm water system easements, incidental access easements, incidental road easements, and incidental utility easements, as may be necessary from time to time, and further excepting land dedicated to public uses through the development process as a condition of development, MCWD, City, and MCWRA shall not seek to acquire fee title to land or easements thereon on any part of the Armstrong Ranch by eminent domain for use in providing water or wastewater service, or for any other public purpose whatsoever, except that, as to City only, said prohibition shall apply only with respect to eminent domain for water or sanitary sewer facilities and shall not be applicable to eminent domain for other public purposes; provided, however, that in the event that any of said agencies shall, notwithstanding the foregoing covenant, warranty and representation, seek to exercise the power of eminent domain for any other purpose except as excepted above, then, and in that event, all Parties hereto hereby agree that the fair market value of and the price to be paid for all such land lying within MCWD Reserved Area as shown on Exhibit "F" hereto (and any additional area shown on an exhibit to a fully executed addendum to this Agreement and Framework) shall be the sum of Twenty-Five Thousand Dollars ($25,000.00) cash per acre and the fair market value and purchase price for all land lying outside of said MCWD Reserved Area as shown on Exhibit "F" hereto (and any additional area shown on an exhibit to a fully executed addendum to this Agreement and Framework) shall be the sum of ONE HUNDRED THOUSAND Dollars ($100,000.00) cash per acre. FURTHERMORE, IN THE EVENT THAT MCWD, CITY, AND MCWRA, OR ANY OF THEM, SHOULD BREACH THIS COVENANT, WARRANTY AND REPRESENTATION, THEN, AND IN THAT EVENT, THE PARTIES AGREE THAT ARMSTRONG SHALL BE ENTITLED TO RECOVER FROM SUCH BREACHING PARTY, AS LIQUIDATED DAMAGES, AN AMOUNT EQUAL TO THE DIFFERENCE BETWEEN THE PRICE PER ACRE ACTUALLY PAID AND TWENTY-FIVE THOUSAND DOLLARS ($25,000.00) PER ACRE MULTIPLIED BY THE NUMBER OF ACRES SO TAKEN IN THE CASE OF LAND WITHIN SAID MCWD RESERVED AREA (AND ANY ADDITIONAL AREA SHOWN ON AN EXHIBIT TO A FULLY EXECUTED ADDENDUM TO THIS AGREEMENT AND FRAMEWORK), AND THE DIFFERENCE BETWEEN THE PRICE PER ACRE ACTUALLY PAID AND ONE HUNDRED THOUSAND DOLLARS ($100,000.00) PER ACRE MULTIPLIED BY THE NUMBER OF ACRES TAKEN IN THE CASE OF LAND LYING OUTSIDE OF MCWD RESERVED AREA (AND ANY ADDITIONAL AREA SHOWN ON AN EXHIBIT TO A FULLY EXECUTED ADDENDUM TO THIS AGREEMENT AND FRAMEWORK), AS LIQUIDATED DAMAGES, WHICH THE PARTIES AGREE IS A REASONABLE SUM CONSIDERING ALL THE CIRCUMSTANCES EXISTING ON THE DATE OF THIS AGREEMENT AND FRAMEWORK, INCLUDING THE RELATIONSHIP OF THE SUM TO THE RANGE OF HARM TO ARMSTRONG THAT REASONABLY COULD BE ANTICIPATED AND THE ANTICIPATION THAT PROOF OF ACTUAL DAMAGES WOULD BE COSTLY OR INCONVENIENT. IN PLACING THEIR SIGNATURES BELOW, EACH PARTY SPECIFICALLY CONFIRMS THE ACCURACY OF THE STATEMENTS MADE ABOVE AND THE FACT THAT EACH PARTY WAS REPRESENTED BY COUNSEL WHO EXPLAINED THE CONSEQUENCES OF THIS LIQUIDATED DAMAGES PROVISION AT THE TIME THIS AGREEMENT AND FRAMEWORK WAS MADE.

ARMSTRONG

MCWD

CITY

MCWRA

6.11. Annexation of portions of Armstrong Ranch used by MCWD. Notwithstanding any other provision of this section 6, portions of the Armstrong Ranch owned and/or used by MCWD may be annexed to the Zones at any time, upon MCWD's written request for such annexation, and after compliance with all then-applicable laws. Any annexation fees or charges by MCWRA for such annexed lands shall be paid by MCWD.

7. TERMS AND CONDITIONS--LONESTAR.

7.1. Compliance with Agency Act Section 22. The MCWRA acknowledges that it may not object to any withdrawal by Lonestar permitted by this section 7, except in compliance with section 22 of the Agency Act. All groundwater withdrawn from the Basin by Lonestar may be used only within the Basin.

7.2. Quantity Limitations. Commencing on the effective date of this Agreement and Framework, Lonestar shall limit withdrawal and use of groundwater from the Basin to Lonestar's historical use of 500 afy of groundwater.

7.3. Annexation of Lonestar Property to the Zones. Approval of this Agreement and Framework by the MCWRA Board of Supervisors shall constitute approval for annexation of the Lonestar Property in accordance with the terms of this Agreement and Framework. The actual annexation will occur as follows: The Lonestar Property annexation to the Zones will not take effect until the Lonestar Property has been approved for prior or concurrent annexation into MCWD. When such approval has been

6.11. Annexation of portions of Armstrong Ranch used by MCWD. Notwithstanding any other provision of this section 6, portions of the Armstrong Ranch owned and/or used by MCWD may be annexed to the Zones at any time, upon MCWD's written request for such annexation, and after compliance with all then-applicable laws. Any annexation fees or charges by MCWRA for such annexed lands shall be paid by MCWD.

7. TERMS AND CONDITIONS--LONESTAR.

7.1. Compliance with Agency Act Section 22. The MCWRA acknowledges that it may not object to any withdrawal by Lonestar permitted by this section 7, except in compliance with section 22 of the Agency Act. All groundwater withdrawn from the Basin by Lonestar may be used only within the Basin.

7.2. Quantity Limitations. Commencing on the effective date of this Agreement and Framework, Lonestar shall limit withdrawal and use of groundwater from the Basin to Lonestar's historical use of 500 afy of groundwater.

7.3. Annexation of Lonestar Property to the Zones. Approval of this Agreement and Framework by the MCWRA Board of Supervisors shall constitute approval for annexation of the Lonestar Property in accordance with the terms of this Agreement and Framework. The actual annexation will occur as follows: The Lonestar Property annexation to the Zones will not take effect until the Lonestar Property has been approved for prior or concurrent annexation into MCWD. When such approval has been

obtained, Lonestar shall notify MCWRA, and the MCWRA Board of Supervisors shall declare by resolution the effective date of the annexation.

7.4. Annexation fee.

7.4.1. Amount of original annexation fee. When the Lonestar Property has been annexed to the Zones, Lonestar will pay to MCWRA an annexation fee computed as follows:

104 acres x $277 (land fee)	=	$ 28,808
264 acres x $27.70 (open space)	=	7,313
500 afy x $783/3 (water charge)	=	130,500
Total principal (original fee)	=	166,621
Total interest @ 6%	=	57,370
Total payment	=	223,991
Semi-annual payments	=	11,200

7.4.2. Choice of lump sum or installment. Lonestar may elect to pay the annexation fee in one lump sum or may pay in semi-annual installments.

7.4.3. Lump sum payment. If paid in a lump sum, the original annexation fee shall be due and payable in full on July 1, next succeeding the first March 1 after the effective date of the annexation. Lonestar may elect to pay the annexation fee in full in one lump sum by giving written notice of such election to MCWRA not later than the May 1 immediately preceding the date payment in a lump sum would be due. Any late payment shall bear interest at the annual rate of 6% from the due date, and shall be subject to the same penalties and collection procedures as are set forth in paragraph 7.4.4.

7.4.4. Installment payments.

7.4.4.1. If the original annexation fee or any addition thereto is paid in installments, the installments shall include interest on the unpaid principal balance at the annual rate determined pursuant to this Agreement and Framework. The interest rate on installments on the original annexation fee shall be six (6) percent per annum and shall begin to accrue on July 1, next succeeding the first March 1 after the effective date of the annexation. The interest rate for the additional water charge shall be equivalent to that which the County would pay for funds borrowed at the time the additional water charge is determined and shall begin to accrue at the beginning of the applicable payment period. The interest included in each installment shall be calculated as though the installment were paid on the last day before delinquency, even if the installment is paid in advance of that date.

7.4.4.2. The amount of each semi-annual installment shall be sufficient to amortize the full amount of principal and interest in twenty (20) equal semi-annual installments.

7.4.4.3. The semi-annual installments shall be paid and collected at the same time and in the same manner and by the same persons as, and together with and not separately from, general agency and zone taxes and shall be delinquent at the same time and thereafter subject to the same delinquency penalties. The first installment shall be due on November 1 following July 1, next succeeding the first March 1 after the effective date of the annexation and shall be delinquent if not paid on or before the following December 10. The second installment shall be due on the following February 1 and shall be delinquent if not paid on or before the following April 10. Thereafter, installments shall fall due and become delinquent on the same dates each year.

7.4.4.4. The full amount of principal and interest shall be paid not later than April 10, in the tenth year following July 1, next succeeding the first March 1 after the effective date of the annexation.

7.4.4.5. The amount of each installment shall constitute a lien on the annexed property as of noon on the March 1 immediately preceding the fiscal year (July 1-June 30) in which payment of the installment will be due. If the property is subdivided, then a prorata share of the annexation fee shall become a lien on each individual parcel, based upon the ratio that the land area of the individual parcel bears to the total land area of all parcels against which the annexation fee is a lien. All laws applicable to the levy, collection and enforcement of general agency and zone taxes, including, but not limited to, those pertaining to delinquency, correction, cancellation, refund and redemption, shall be applicable to such installments.

7.4.5. <u>Additional annexation fee for change in water use</u>. If the water use on the Lonestar Property is changed from an industrial or agricultural use to a potable or other use, or if MCWD delivers potable water to the Lonestar Property pursuant to paragraph 5.1.1.3., then Lonestar shall pay to the MCWRA as an additional annexation fee, an additional water charge computed as two-thirds (2/3rds) of the product of 500 afy multiplied by the then-current annexation water charge. If Lonestar uses water on the 264-acre open-space area, Lonestar shall pay an additional land fee of nine times the land fee specified for the area in 7.4.1. above. The additional water charge or land fee will be paid either in one lump sum, due and payable on July 1, immediately following the change in water use, or in twenty (20) equal semi-annual installments over ten (10) years, with the payment period and interest accrual beginning on that July 1, in the same manner as prescribed for Lonestar's original annexation fee and subject to the same rules.

7.4.6. Additional annexation fee for Mitigation Plan water supply allocation. If a substitute supply of potable Mitigation Plan water is approved for the Lonestar Property pursuant to Section 22 of the MCWRA Act, then, when the contract for construction of the Mitigation Plan has been approved by the MCWRA Board of Supervisors, and when Lonestar begins using water for potable uses, Lonestar will pay as an addition to its annexation fee an additional water charge computed as two-thirds (2/3rds) of the product of the amount so allocated multiplied by the then-current annexation water charge. The additional water charge will be paid either in one lump sum, due and payable on July 1, immediately following approval of both the Mitigation Plan water supply for Lonestar and the construction contract for the Mitigation Plan, or in twenty (20) equal semi-annual installments over ten (10) years, with the payment period and the interest accrual beginning on that July 1, in the same manner as prescribed for Lonestar's original annexation fee and subject to the same rules.

7.4.7. Non-duplication of additional annexation fees. The additional annexation fees set forth in paragraphs 7.4.5 and 7.4.6 above are not intended to be cumulative. If Lonestar becomes liable to pay both of the additional annexation fees, then Lonestar shall be obligated to pay only the higher of the two fees, and any amounts previously paid towards the lower additional fees shall be credited towards payment of the higher.

8. TERMS AND CONDITIONS--GENERAL.

8.1. Equal treatment by MCWRA and MCWD. If future litigation, regulation or other unforeseen action diminishes the total water supply available to MCWRA, MCWRA agrees that it will exercise its powers so that MCWD, Armstrong and Lonestar shall be no more severely affected in a proportional sense than other lawful users of water from the Zones, based on the right before the imposition of any uniform and generally applicable restrictions as described in paragraph 8.2 to use at least the quantities of water from the Basin described in paragraphs 5.1., 6.9., and 7.2. MCWRA shall not at any time seek to impose greater restrictions on water use from the Basin by MCWD, Armstrong or Lonestar than are imposed on users either supplying water for use or using water within the city limits of the City of Salinas. MCWD, Armstrong and Lonestar will comply with any basin-wide or area-wide water allocation plans established by the MCWRA which include MCWD, Armstrong and Lonestar, and which do not impose on use of water on the lands described in Exhibits "B", "C", and "D" restrictions greater than are imposed on users either supplying water for use or using water within the City of Salinas, and which satisfy the requirements of paragraph 5.2 of this Agreement and Framework.

8.2. Water Conservation Measures. MCWD, Armstrong and Lonestar shall use, and MCWD may require the use of reasonable and appropriate water conservation measures on the lands described in Exhibits "B", "C" and "D" to this Agreement and Framework, which water conservation measures shall be uniformly applied and may be more restrictive but shall not be less restrictive than measures implemented by MCWRA as part of a Basin-wide or area-wide water conservation program. All planning and environmental review for the lands described in Exhibits "B", "C", and "D" to this Agreement and Framework shall be based on the requirement that development on such lands shall use reasonable and appropriate water conservation measures comparable to measures implemented by MCWRA as part of a Basin-wide or area-wide water conservation program, and by MCWD as part of a water conservation program applicable uniformly within MCWD's service area.

8.3. Defense of Rights. Upon Mitigation Plan Implementation, MCWRA will defend the rights of MCWD, Armstrong and Lonestar to a supply of water from the Mitigation Plan, as though those rights were the rights of MCWRA. Participation by MCWD, Armstrong and Lonestar in the Mitigation Plan or any other alternative water supply plan is subject to compliance with all applicable laws, including but not limited to CEQA.

8.4. Use of Annexation Fees. Annexation fees from the MCWD service area, the Armstrong Ranch and the Lonestar Property shall be used by MCWRA to pay the costs of a BMP process that includes mitigation plans for the Marina Area based on the planning guidelines contained in this Agreement and Framework. Such annexation fees shall also be used for management and protection of the "900-foot aquifer."

8.5. Assessments. After approval by the Board of Supervisors of annexation to the Zones of any property described in the exhibits to this Agreement and Framework, each parcel annexed shall be subject to all uniform assessments, charges, fees, and other exactions levied in Zones 2 and 2A for the fiscal year beginning on July 1, next succeeding the first March 1 after the effective date of the annexation, and shall remain subject thereto for as long as such exactions are levied and the parcel remains within the levying zone.

8.6. Recordation. Upon approval of this Agreement and Framework by the Board of Supervisors and execution by all Parties, this Agreement and Framework shall be recorded in the office of the Monterey County Recorder. All signatures shall be notarized as necessary to record the Agreement and Framework.

9. DISPUTE RESOLUTION PROCEDURE.

9.1. If any dispute arises between the Parties as to the proper interpretation or application of this Agreement and Framework, the Parties shall first seek to resolve the dispute in accordance with this Agreement and Framework, and the Parties must meet and confer under this Agreement and Framework before filing any court action.

9.2. If any dispute under this Agreement and Framework arises, the Parties shall first meet and confer, in an attempt to resolve the matter between themselves. Each party shall make all reasonable efforts to provide to the other Parties all the information that the party has in its possession that is relevant to the dispute, so that all Parties will have ample information with which to reach a decision.

9.3. If, notwithstanding the good faith efforts of a party requesting in writing the resolution of a dispute under this Agreement and Framework, a dispute remains unresolved sixty-one (61) days after delivery of the request to the other party, the party requesting resolution may file suit for legal and equitable relief, including specific performance, as appropriate.

10. CHALLENGE OF LAWS. Nothing herein contained shall be construed as stopping or otherwise preventing any party to this Agreement and Framework from contesting by litigation or other lawful means the validity, constitutionality, construction, or application of any law of this State, any ordinance of the public entities that are Parties hereto, or any rule, regulation or practice of the public entities that are Parties hereto.

11. WAIVER OF RIGHTS. Any waiver at any time by any party hereto of its rights with respect to a default or any other matter arising in connection with this Agreement and Framework shall not be deemed to be a waiver with respect to any other default or matter. None of the covenants or agreements herein contained can be waived except by the written consent of the waiving party.

12. NOTICES. All notices and demands required under this Agreement and Framework shall be deemed given by one party when delivered personally to the principal office of the other party; when faxed to the other party, to the fax number provided by the receiving party; or five days after the document is placed in the United States mail, first class, registered mail, or certified mail, postage prepaid, addressed to the other party as follows:

To MCWD:	11 Reservation Road Marina, CA 93933-2099 Phone No.: (408) 384-6131 Fax No.: (408) 384-2479
To MCWRA:	General Manager P. O. Box 930 Salinas, CA 93902-0930 Phone No.: (408) Fax No.: (408) 424-7935

To City: City Manager
211 Hillcrest Avenue
Marina, CA 93933
Phone No.: (408) 384-3715
Fax No.: (408) 384-0425

To Armstrong: John A. Armstrong
270 River Road
Salinas, CA 93908
Phone No.: (408) 455-1907
Fax No.: (408) 455-2817

To Lonestar: RMC LONESTAR
Attention: Mr. John Rubiales
P.O. Box 5252
Pleasanton, CA 94566
Phone No.: (510) 426-8787
Fax No.: (510) 426-2225

The address or fax number to which any notice or other writing may be given or made or sent to any party may be changed upon written notice given by such party as above provided.

13. SEVERABILITY. If any one or more of the covenants or agreements set forth in this Agreement and Framework on the part of MCWRA, MCWD, City, Armstrong or Lonestar, or any of them, to be performed should be contrary to any provision of law or contrary to the policy of law to such extent as to be unenforceable in any court of competent jurisdiction, then such covenant or covenants, agreement or agreements, shall be null and void and shall be deemed separable from the remaining covenants and agreements and shall in no way affect the validity of this Agreement and Framework; provided, that if voiding of such individual covenants or agreements without voiding the whole agreement would frustrate a material purpose of Lonestar in entering into this Agreement and Framework, then this whole Agreement and Framework shall be null and void ab initio as to Lonestar only.

14. PARAGRAPH HEADINGS. Paragraph headings in this Agreement and Framework are for convenience only and are not to be construed as a part of this Agreement and Framework or in any way limiting or amplifying the provisions hereof.

15. SUCCESSORS AND ASSIGNS. This Agreement and Framework and all the terms, covenants, agreements and conditions herein contained shall inure to the benefit of and be binding upon the successors and assigns of the Parties hereto.

16. ADMINISTRATORS. MCWD and MCWRA hereby designate their respective General Managers as their Administrators for this Agreement and Framework. City designates its City Manager as City's Agreement and Framework Administrator. Armstrong designates Mr. John A. Armstrong as its Agreement and Framework Administrator. Lonestar designates Mr. John Rubiales as its Agreement and

Framework Administrator. All matters concerning this Agreement and Framework shall be submitted to the Agreement and Framework Administrators or such other representatives as the Agreement and Framework Administrators may designate for their respective agencies. Any party may, in its sole discretion, change its designation of the Agreement and Framework administrator and shall promptly give written notice to the other Parties of any such change.

17. NEGOTIATED AGREEMENT AND FRAMEWORK. This Agreement and Framework has been arrived at through negotiation between the Parties. Neither party is to be deemed the party which prepared this Agreement and Framework within the meaning of Civil Code section 1654.

18. AMENDMENT. This Agreement and Framework may be amended only by a writing signed by the Parties affected by the amendment.

19. COUNTERPARTS. This Agreement and Framework may be executed in counterparts. Each fully executed counterpart shall be deemed a duplicate original, and all counterparts which together contain the signatures of all the Parties shall be deemed, when attached together, one complete and integrated original document.

20. ADDENDUM. A form of Addendum for the MRWPCA is attached hereto as Exhibit "G." When the Addendum is fully executed in its present form or in an amended form, it shall be attached to this Agreement and Framework as an integral part of this Agreement and Framework, and the provisions of the Addendum shall be deemed specifically and fully incorporated into this Agreement and Framework by this reference.

IN WITNESS WHEREOF, the Parties execute this Agreement and Framework as follows:

EXHIBIT "D1"

LEGAL DESCRIPTION - LANDS OF RMC-LONESTAR

(based on preliminary report from Western Title Insurance Company dated December 12, 1986)

Said land is situate in the County of Monterey, State of California, and is described as follows:

PARCEL 1

A part of Monterey City Lands Tract No. 1 embracing the sand dunes along the shore of Monterey Bay, described as follows, to-wit:

BEGINNING at the common corner of the Rancho Rincon de las Salinas and the Monterey City Lands Tract No. 1 on the shore of Monterey Bay, from which an old Four inch by Four inch post marked "R S 3 Wit" standing on Rancho boundary bears South 63° 20′ East Twelve and 79/100 chains distant; thence Variation 16° 50′ East, following the shore line of bay South 1° 05′ West Sixty and 00/100 chains to station; thence South 5° 40′ West Thirty-three and 00/100 chains to station; thence South 11° 30′ West Thirty-one and 02/100 chains to the Northerly boundary of the land of David Jacks; thence leaving the shore of the Monterey Bay and following the fence along the Northerly line of the land of David Jacks Corporation South 65° 30′ East, Twenty-three and 61/100 chains to station; thence South 65° 12′ East Five and 31/100 chains a Four inch by Four inch post marked "E. B. & A. L. S. Cor. No. 1" standing at the foot of sand hills and at the Easterly side thereof, Seven and 23/100 chains to station from which the point of intersection of Jacks boundary fence with the center line of the S. P. R. R. at station 281 plus Fifty-one and 6/10 bears South 65° 12′ East Fifty-one and 73/100 chains distant; thence leaving the Jacks boundary and following the old fence skirting the Easterly side of sand dunes North 7° 30′ East Eleven and 00/100 chains; thence North 15° 15′ East Five and 87/100 chains to station; thence North 34° East Six and 92/100 chains to station; thence North 11° 30′ East One and 00/100 chains to station; thence North 5° 45′ West Five and 18/100 chains to station; thence North 12° 15′ East Five and 66/100 chains to station; thence North 4° West 3 and 60/100 chains to station; thence North 34° East One and 27/100 chains to station; thence North 14° 30 East Three and 29/100 chains to station; thence North 6° 45′ West Three and 83/100 chains to center line of Lapis Spur track; thence North 0° 15′ East Five and 51/100 chains to station; thence North 22° 30′ East Four and 10/100 chains to station; thence North 16° 45′ East Five and 05/100 chains to station; thence North 34° East Four and 17/100 chains to station; thence North 13° East Ten and 15/100 chains to station; thence North 30° 45′ East Two and 45/100 chains to station; thence North 13° 40′ East Two and 72/100 chains to an old fence corner; thence North 9° 35′ West One and 83/100 chains to station 17; thence North 9° 35′ West Twenty-seven and 60/100 chains to station 18; thence North 32° 40′ East Five and 21/100 chains to station 19; thence North 70° East Two and 27/100 chains to station 20; thence North 46° 50′ East Two and 16/100 chains to station 21; thence North 12° 45′ West Three and 05/100 chains to station 22; thence North 26° 30′ East One and 92/100 chains to a Four inch by Four inch post marked E. B. & A. L. S. Cor. No. 23" standing in the fence on the line between the Monterey City Lands and the Rancho Rincon de las Salinas, thence leaving foot of sand hills and following said line fence across same North 63° 20′′ West Forty-two and 02/100 chains to the place of beginning.

PARCEL 2

All those certain lots, pieces or parcels of land situate, lying and being in the County of Monterey, State of California, described as follows:

A PART of Monterey City Lands Tract No. 1, described as follows:

A strip of land one hundred feet wide measured at right angles to and lying fifty feet on each side of a line located and described as follows:

BEGINNING at a point on the Eastern boundary of the piece of land here-in-before described as Parcel 1, said point bearing North 6° 45′ West from station numbered 9 on said boundary line and distant Two hundred fifty-two and 5/10 feet therefrom thence by a straight line bearing South 77° 29′ East Five hundred seventy-nine and 38/100 feet; thence by a 6° 00′ curve to the left (radius 955.04 feet), Five hundred seventy-six and 81/100 feet; thence by a straight line bearing North 67° 54-1/2′ East Six hundred forty-eight and 08/100 feet; thence by a 5° 00′ curve to the left (radius 1146.01 feet) Eleven hundred thirty-nine and 2/10 feet, more or less, to the Western line of the Southern Pacific Company's Railroad right of way.

EXCEPTING THEREFROM that portion conveyed to the State of California by deed dated May 31, 1974 and recorded August 19, 1974, on Reel 930, Official Records, at page 909, Monterey County Records.

PARCEL 3

All those certain lots, pieces or parcels of land situate, lying and being in the County of Monterey, State of California, described as follows:

All that portion of Monterey City Lands Tract No. 1 lying between the Western boundary line of Parcel 1 of the property described in the deed from John A. Armstrong et al, to E. B. & A. L. Stone Company, a corporation, dated January 24, 1907, and recorded January 24, 1907 in Liber 95 of Deeds, page 388, and the Western boundary line of the property patented to the City of Monterey, by patent, dated November 19, 1891, and recorded November 16, 1896 in Liber "F" of patents at page 178.

PARCEL 4

All those certain lots, pieces or parcels of land situate, lying and being in the County of Monterey, State of California, described as follows:

All that part of Monterey City Lands Tract No. 1 described as follows:

BEGINNING at a Four inch by Four inch post marked "B 6" standing in the Eastern Boundary of the certain 399.70 acre tract conveyed by J. G. Armstrong Co., a corporation, to the E. B. & A. L. Stone Co., a corporation by deed dated January 31, 1911, and recorded in volume 117, of Deeds at page 283, Monterey County Records, from which station 9 of said boundary bears South 6° 45′ East one hundred ninety-five and 08/100 feet distant; thence along said Eastern boundary North 6° 45′ West Fifty-seven and 7/10 feet to a station in center line of one hundred foot right of way as shown in above mentioned deed; thence North 0° 15′ East, still along said Eastern boundary three hundred sixty-three and 6/10 feet to a station; thence North 22° 30′ East one hundred seven and 0/10 feet to a four inch by four inch post marked "B 1" in said Eastern boundary; thence leave said boundary South 29° 50′ East three hundred ninety-two and 2/10 feet to a four inch by four inch post marked "b 2"; thence South 45° 29′ East one hundred thirty-one and 0/10 feet to a four inch by four inch post marked "B 3"; thence South 77° 40′ East two hundred seventy-six and 0/10 feet to a four inch by four inch post marked "B 4"; thence South 12° 20′ West, at fourth-nine and 9/10 feet to the Northern line of above mentioned one hundred foot right of way at one hundred forty-nine and 9/10 feet the Southern line of same, one hundred fifty-five and 0/10 feet to a four inch by four inch post marked "b 5", thence North 77° 40′ West, five feet southerly of and parallel with the Southern line of said right of way five hundred seventy-four and 3/10 feet to the place of beginning.

Courses all true variation of magnetic needle being 17° 15′ East. Surveyed by Cozzens & Davies, Salinas, California, March 1922

EXHIBIT E

ELEMENTS OF YEARLY INCREMENTAL COSTS
FOR ADD-ON OF RECLAIMED WATER FOR M & I PUROSES OVER AND ABOVE THAT COMMITTED TO THE CASTROVILLLE SEAWATER IRRIGATION PROJECT

1) Operation and Maintenace (O&M) Element of costs to provide tertiary treatment (in \$/acre-foot for the year of ?). Costs for the previous year will be used to estimate the next year costs. An adjustment will be included in the following year to reflect actual costs. The next year flow volume demand for MCWD will be based on a projection submitted by the MCWD to the MCWRA by June 30, three months before delivery of next year reclaimed water to the MCWD reservoir.

- Chemical costs
- Power costs
- Sludge management costs
- Labor costs
- Repair and replacement costs

$$\text{O\&M ELEMENT (in \$/acre-foot)} = \frac{\sum \text{chemicals + power + sludge mgmt. + labor + repair \& replacement costs}}{\text{Projected Next Year Flow Volume Demand [CSIP(afy) + MCWD(afy)]}} \pm \text{adjustment for previous year}$$

2) Bureau of Reclamation Loan Element (BRLE). Includes Reimbursible Interest During Construction (RIDC) and Emergency Reserve Fund Contribution (ERFC) in \$ / acre-foot for the year of ?.

$$\text{APPLICABLE ANNUAL PERCENTAGE for M\&I (AAPM\&I)} = \frac{\text{Projected next year flow volume demand for MCWD (afy)}}{\text{Projected Next Year Flow Volume Demand [CSIP(afy) + MCWD(afy)]}}$$

$$\text{BRLE(\$) FOR YEAR (?)} = \frac{\text{AAPM\&I x [PRINCIPAL + INTEREST(7.625\%) ON OUTSTANDING PRINCIPAL + RIDC + ERFC FOR YEAR(?)]}}{\text{Projected next year flow volume demand for MCWD (afy)}}$$

3) Increased capital cost element to cover M&I for the MCWD.

No additional capital costs.

4) Capital Risk Share Element (CRSE) in \$ / acre-foot for the year of ?.

$$\text{CRSE (\$)} = \frac{\text{AAPM\&I x [SVRP Debt Service for State Revolving Fund(Schedule A Line 18)+ 1/3 of Bonds (Schedule A, Line 25) FOR YEAR(?)]}}{\text{Projected next year flow volume demand for MCWD (afy)}}$$

EXHIBIT "F"

EXHIBIT G

MONTEREY REGIONAL WATER POLLUTION CONTROL AGENCY ADDENDUM TO

ANNEXATION AGREEMENT AND GROUNDWATER MITIGATION FRAMEWORK FOR MARINA AREA LANDS

1. PURPOSE. The Parties to the Agreement and Framework agree with the Monterey Regional Water Pollution Control Agency ("MRWPCA") that it is in the best interests of all of them and the persons they represent if the MRWPCA is also a party to the Agreement and Framework, with certain additional terms specific to the MRWPCA. If this Addendum is approved by the MRWPCA within one year of approval of the Agreement and Framework and this Addendum by the other Parties, this Addendum will become part of the Agreement and Framework, and the MRWPCA will be considered a party to the Agreement and Framework, effective from the date the Agreement and Framework and this Addendum are approved by the Board of Supervisors of the MCWRA.

2. MRWPCA. MRWPCA is a joint powers authority providing sewage treatment service to its member entities in Northern Monterey County, governed by its Board of Directors.

3. MRWPCA SUPPORT FOR ANNEXATION. MRWPCA is supporting the request for annexation contained in paragraph 4.1 of the Agreement and Framework to encourage reasonable and beneficial water reuse, and to help implement the MCWRA/MRWPCA Agreement, the MRWPCA Annexation Agreement, and the SVRP.

4. RESERVATION FOR MRWPCA. Armstrong shall reserve, for use by MRWPCA, the area shown diagrammatically on Exhibit "I" to this Addendum (hereinafter the "MRWPCA Reserved Area"), subject to the non-exclusive easements shown on Exhibit "I" to be reserved in favor of Armstrong and MCWD, which said reserved easements in favor of Armstrong and MCWD shall be for roads, utilities (including communications), pipelines, and any other purpose for which a road may be used, shall be freely assignable and usable by others, and not subject to surcharge.

4.1. Survey. The MRWPCA Reserved Area, which shall not exceed 10 acres, will be "field" surveyed at the expense of MRWPCA within one year following approval by the MCWRA Board of Supervisors of the annexation to the Zones of any of the lands described in Exhibit "C" to the Agreement and Framework.

4.2. Use. MRWPCA will diligently undertake, and MCWD, City, MCWRA and Armstrong will cooperate in the planning and conduct of, the appropriate environmental review and application for appropriate permits to use the MRWPCA Reserved Area solely and exclusively as a buffer zone between the existing Regional Treatment Plant and the Armstrong Ranch. Any additional use is subject to the written approval of Armstrong first had and obtained, and any conveyance from Armstrong to MRWPCA shall contain appropriate restrictions on such additional use in the form of a condition subsequent and a power of termination in favor of Armstrong. Any attempt to condemn the power of termination shall be subject to the provisions of paragraph 6.10.3 as if it were a condemnation of fee title.

4.3. Expiration of Reservation. Armstrong's obligation to reserve the MRWPCA Reserved Area shall expire at midnight on June 30, 2003, or upon delivery to Armstrong of written notice from MRWPCA cancelling MRWPCA's right to receive conveyance of the MRWPCA Reserved Area.

4.4. Payment. Upon conveyance of the MRWPCA Reserved Area to MRWPCA, MRWPCA shall pay to Armstrong a sum calculated by multiplying the number of acres in such conveyance by Twenty-Five Thousand Dollars ($25,000.00).

4.5. Title. Upon receipt by Armstrong of written request from MCWD, Armstrong will forthwith convey all or part of the MRWPCA Reserved Area to MRWPCA by grant deed, free of any financial encumbrances except taxes and assessments not delinquent, but subject to all other encumbrances, and further subject to all laws, ordinances, regulations and rights of all governmental bodies having jurisdiction in, on or over the subject real property as they may from time to time exist.

5. ATTACHMENT TO AGREEMENT AND FRAMEWORK; INCORPORATION BY REFERENCE. When this Addendum is fully executed, it shall be attached to the Agreement and Framework as an integral part of the Agreement and Framework, and the provisions of Sections 1, 2, 3, 8, and 9 through 20, inclusive, and paragraphs 4.5, 5.6, 5.7 and 6.10.3 of the Agreement and Framework are specifically incorporated into this Addendum by this reference and shall apply to the terms of this Addendum and as fully to MRWPCA as though MRWPCA had signed the Agreement and Framework. A person duly authorized by MRWPCA places his or her initials here to indicate MRWPCA's specific agreement to the provisions of paragraph 6.10.3:

Signature: ______________________________

Printed Name and Title: ______________________________

STATE OF CALIFORNIA) ss.
COUNTY OF MONTEREY)

On this 26th day of March, 1996, before me, Ernest K. Morishita, Clerk of the Board of Supervisors, in and for said County and State, personally appeared Edith Johnsen, known to me to be the Chairperson of said Board of Supervisors of the County of Monterey, and known to me to be the person who executed the within instrument on behalf of said political subdivision, and acknowledged to me that such County of Monterey executed the same.

ERNEST K. MORISHITA, Clerk of the
Board of Supervisors of Monterey
County, State of California

By: Pamela Olivas
Deputy Clerk

6. <u>NOTICES</u>. Notices to MRWPCA under this Addendum and the Agreement and Framework shall be addressed as follows:

General Manager
5 Harris Court, Building D

Appendix 5-A

Relationship between Total Dissolved Solids and Chloride in the Lower 180-Foot/400-Foot Aquifer in the Monterey Subbasin

Appendix 5-A
Relationship between Total Dissolved Solids and Chloride in the Lower 180-Foot/400-Foot Aquifer within the Monterey Subbasin

GSP Emergency Regulations require that (1) Seawater Intrusion minimum threshold to be established using a chloride concentration isocontour (§354.28 (c)(3)).and that (2) monitoring of Seawater Intrusion to be "using chloride concentrations, or other measurements convertible to chloride concentrations…" (§354.34 (c)(3)) The Monterey Subbasin Groundwater Sustainability Plan (GSP) intends to use total dissolved solids (TDS) concentration data as a proxy for determining seawater intrusion where chloride data is unavailable. Therefore, this memorandum examines historic chloride and TDS data within the seawater intruded lower 180-Foot/400-Foot Aquifer of the Monterey Subbasin and establishes a relationship between elevated TDS and chloride concentrations within this aquifer.

TDS and chloride data from wells that meet the following criteria within the Monterey Subbasin are selected for this analysis:

- Has at least 15 TDS and/or chloride measurements; and
- Is screened in the lower 180-Foot/400-Foot Aquifer.

A total of 71 wells met the criteria above. Within these 71 wells, this analysis compiled TDS and chloride concentrations that were sampled at each well during the same sampling event (i.e. "TDS-CL measurement pairs"). The distribution of the number of TDS-CL measurement pairs for these 71 wells are shown in Figure 5A-1 below. As shown on Figure 5A-1, there is an abundance of wells with TDS-CL measurement pairs.

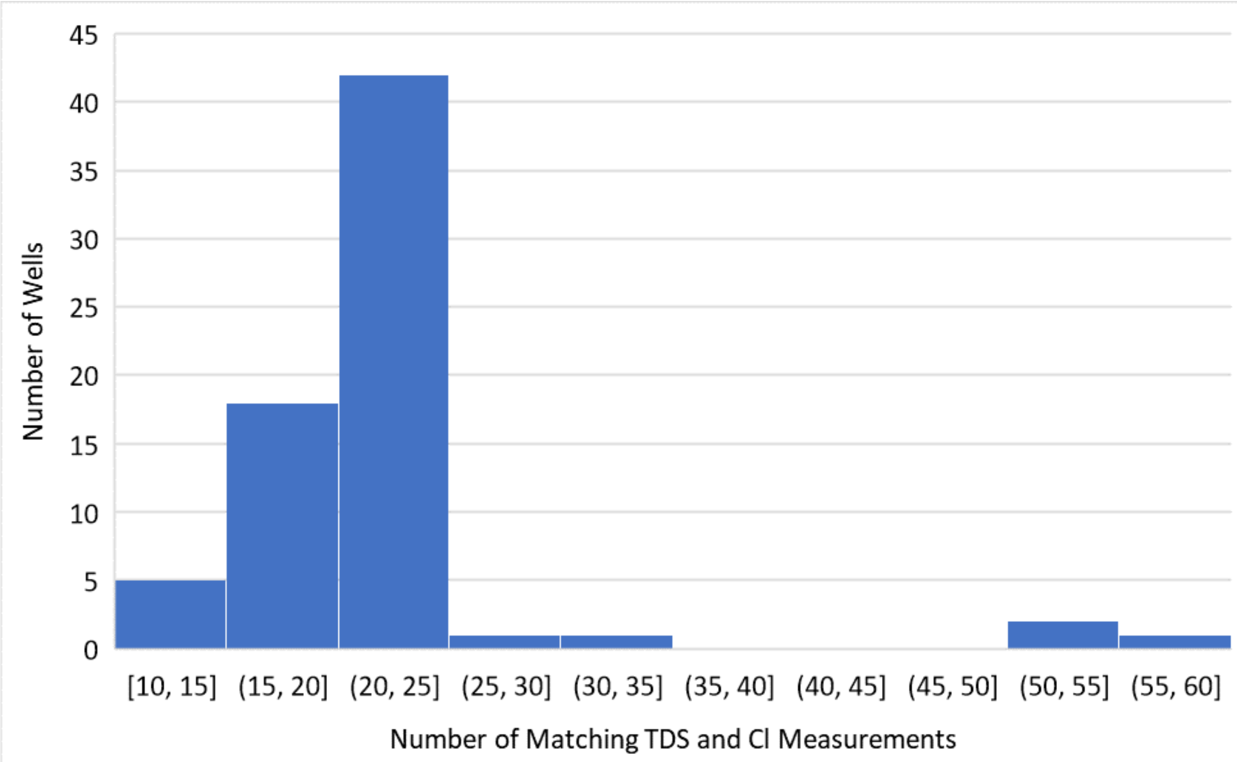

Figure 5A-1. Distribution of TDS-CL Measurement Pairs

Figure 5A-2 analyzes the temporal distribution of these TDS-CL measurement pairs. As shown on Figure 5A-2, very limited TDS-CL measurement pairs were collected beyond 2008, which is especially due to the lack of chloride data during this period. However, a large quantity of TDS-CL measurement pairs data was collected between 2002 and 2008.

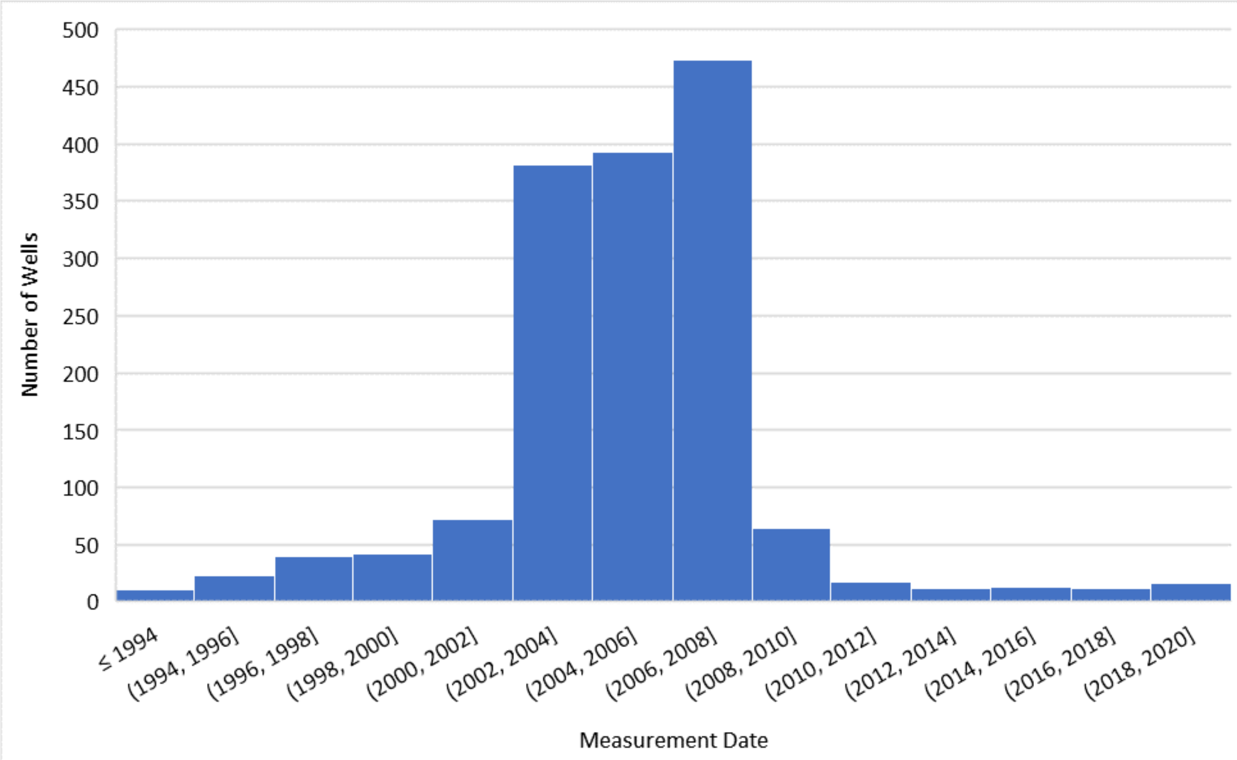

Figure 5A-2. Distribution of TDS-CL Measurement Dates

With the existing TDS-CL measurement pairs data, Figure 5A-3 shows a scatter plot of TDS and chloride concentrations[1] in lower 180-Foot/400-Foot Aquifer wells. As shown in Figure 5A-3 below, there is a strong positive linear relationship between chloride concentration and TDS concentration.

[1] Average concentrations were computed for wells that have duplicate measurements.

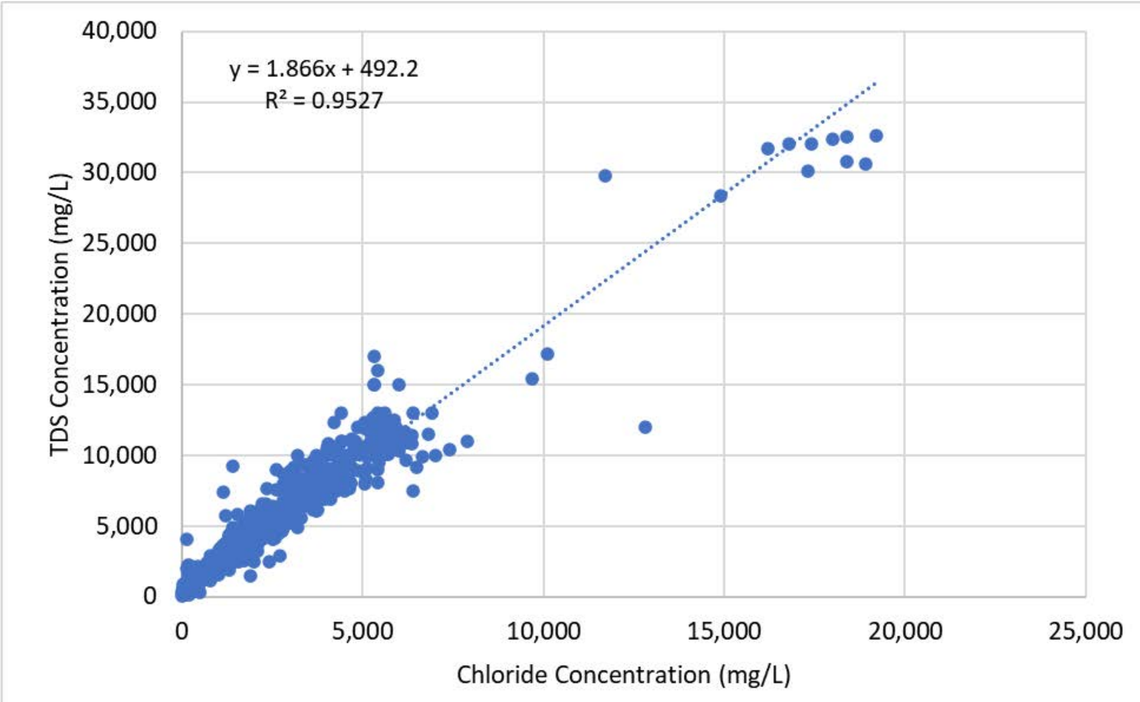

Figure 5A-3. TDS vs. Chloride Concentration, Linear Scale

To examine this relationship further, the below (Figure 5A-4) plots the TDS and chloride concentrations on a log-log scale. As shown on this graph, the TDS-chloride concentrations relationship weakens at very low (below 100 mg/L) chloride concentrations. This is consistent with the fact that a certain level of TDS is associated with other naturally occurring constituents. It appears that the natural TDS within this aquifer is low, at approximately 300 mg/L TDS. Increase in TDS concentrations above this level is strongly correlated to chloride concentration increases.

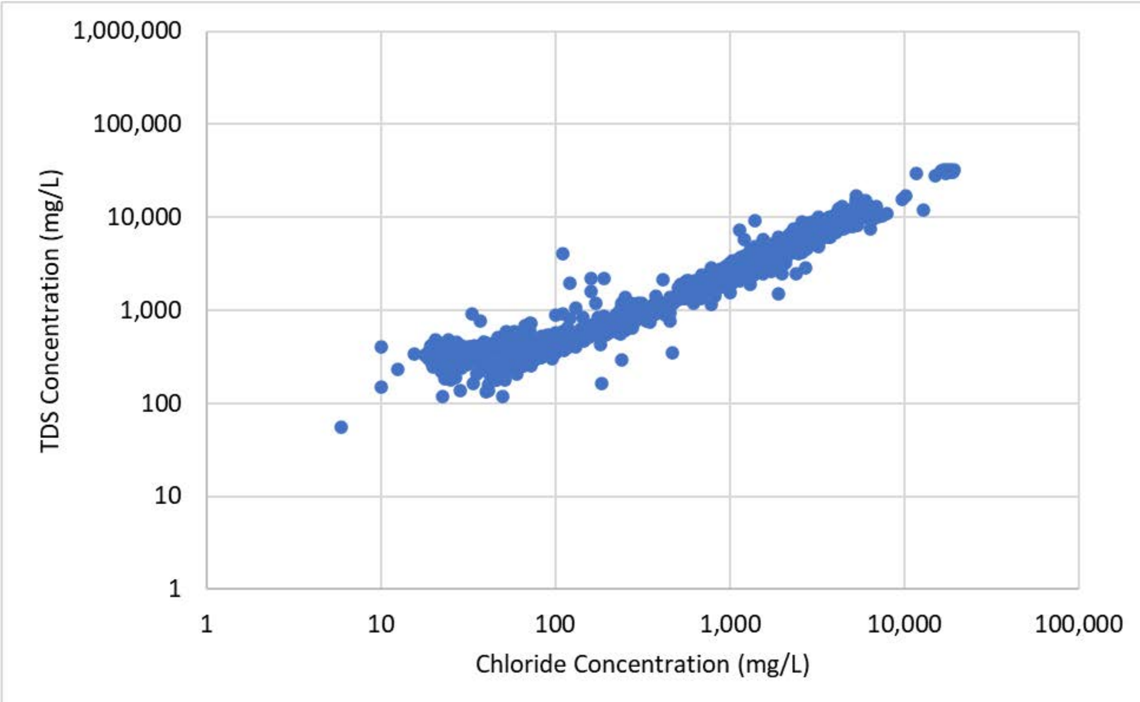

Figure 5A-4. TDS vs. Chloride Concentration, Log-Log Scale

Therefore, a trendline is fitted to these historic TDS-CL measurements within the lower 180-Foot/400-Foot Aquifer assuming a natural TDS at 300 mg/L (Figure 5A-5). The fitted relationship establishes a conversion between TDS and chloride concentration within this aquifer, and is as follows:

$$TDS\ (mg/L) = 1.91 \times Chloride\ (mg/L) + 300$$

The Monterey Subbasin GSP adopts a seawater intrusion definition at of 500 mg/L chloride. Based on this relationship, it can be concluded that (1) elevated TDS concentration that is significantly above 300 mg/L in the lower 180-Foot/400-Foot Aquifer is associated with increases in chloride concentration; and (2) a TDS concentration at approximately 1,250 mg/L in this aquifer is equivalent to a chloride concentration at 500 mg/L.

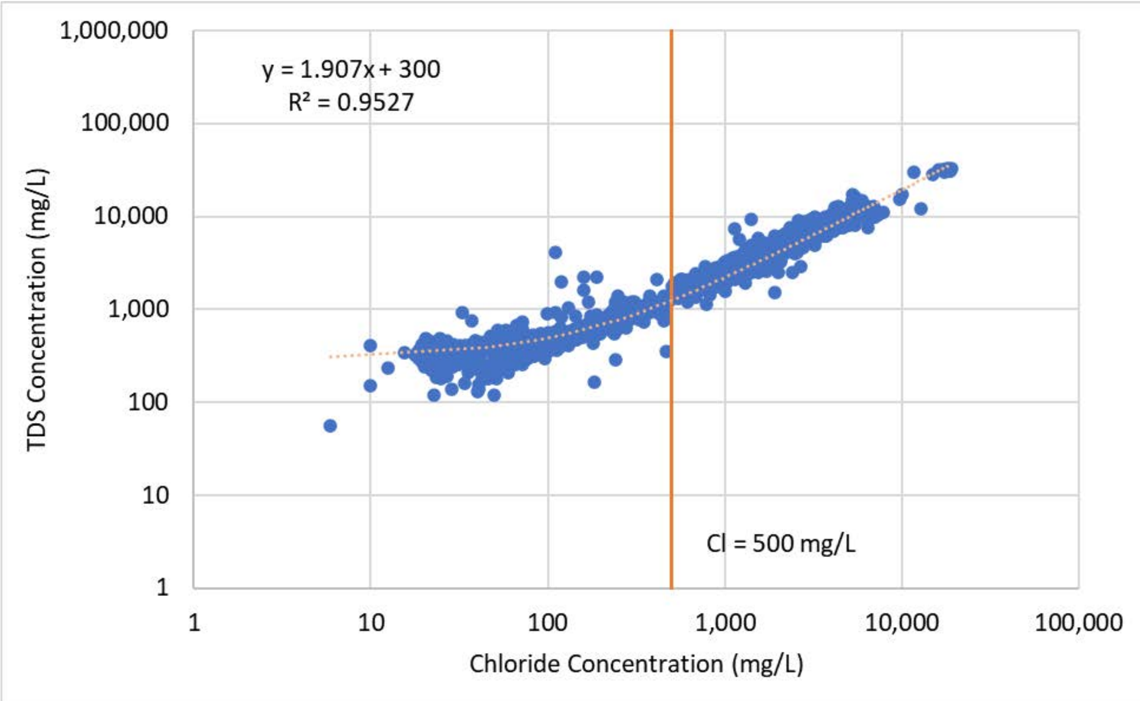

Figure 5A-5. TDS vs. Chloride Concentration, Log-Log Scale with Trendline

AVERAGE (AFY)	-	**10,055**	**-5,641**	**-8,848**	**0**	**-4,434**	-

Abbreviations

AF = acre-feet
AFY = acre-feet per year
DWR = California Department of Water Resources
WBZ = Water Budget Zone
WY = Water Year

DWR Water Year Type

(green)	= Wet
(light green)	= Above Normal
(light yellow)	= Below Normal
(light pink)	= Dry
(red)	= Critical

Notes:

(1) All values in acre-feet per year (AFY) unless otherwise noted.
(2) Water Year Types were developed from the DWR method defined in DWR, 2021 and are classified as follows: W = Wet, AN = Above Normal, BN = Below Normal, D = Dry, C = Critical. Colors indicate Water Year Type where green is wetter and red is drier.

1. MODEL DEVELOPMENT OVERVIEW

The Monterey Subbasin Groundwater Flow Model (MBGWFM or "model") is an approximation of the spatial extent and variability of the groundwater system in the Monterey Subbasin (Basin) and can be used to quantitatively evaluate local hydrogeologic conditions associated with water inflows, outflows, and associated connectivity between the adjacent Seaside Subbasin, 180/400-Foot Aquifer Subbasin, and the Pacific Ocean. The purpose of the MBGWFM is to quantify the historical, current, and projected water budgets for the Basin and their uncertainties, and to evaluate the impacts of future land use, hydrologic, and water supply/demand projections as well as any proposed management decisions on groundwater conditions within the Basin. The model can also help identify gaps in available data and deficiencies in the conceptual understanding of groundwater conditions in the Basin. These results help prioritize plans for future data collection and other Groundwater Sustainability Plan (GSP) implementation activities.

1.1 Use of Information from SVIHM

Some results from the Salinas Valley Integrated Hydrologic Model (SVIHM) were used in developing the MBGWFM or to compare with results from the MBGWFM. It is important to note that the SVIHM results utilized are preliminary and draft. The SVIHM is being developed by the U.S. Geological Survey (USGS). A written disclaimer for the SVIHM has been provided by the USGS and is excerpted below:

> *This data (model and/or model results) are preliminary or provisional and are subject to revision. This model and model results are being provided to meet the need for timely best science. The model has not received final approval by the USGS. No warranty, expressed or implied, is made by the USGS or the U.S. Government as to the functionality of the model and related material nor shall the fact of release constitute any such warranty. The model is provided on the condition that neither the USGS nor the U.S. Government shall be held liable for any damages resulting from the authorized or unauthorized use of the model.*

2. METHODOLOGY AND APPROACH

2.1 Model Source Code

The MBGWFM utilizes the United States Geological Survey (USGS) computer code MODFLOW-NWT (Niswonger et al., 2011); MODFLOW is a widely used model code and is publicly available and supported by the USGS. MODFLOW-NWT is a Newton formulation of MODFLOW-2005 which excels at solving models whose cells have active drying and rewetting in the unconfined groundwater flow equation (Niswonger et al., 2011). As the Basin has variable degrees of confinement depending on aquifer formation and location, MODFLOW-NWT is an appropriate and effective computer code to solve the groundwater flow equation.

MODFLOW-NWT's utility is enhanced by additional software processes for model development, processing, and analysis of results. Specifically, ZONEBUDGET version 3 (Harbaugh, 1990) is a post-processor used to extract water budget results for user-defined model subareas.

As discussed in more detail in *Section 3.1* and ***Attachment 2***, a soil moisture balance code was developed to represent the root zone processes and ultimately create the recharge datasets within the MBGWFM.

2.2 Discretization

When employing numerical models, the spatial domain is discretized into "model cells" and time is discretized into "stress periods". The discretization of the spatial domain is referred to as the spatial approach and the discretization of time is referred to as the temporal approach. Both approaches are further discussed below.

2.2.1 Spatial Approach

MODFLOW represents the groundwater system as a set of discrete, rectangular blocks (cells) forming a grid in space. MODFLOW then computes an approximate solution to the groundwater flow mathematical equations at each model cell. The model grid consists of 260 rows and 214 columns of cells that cover the entire extent of the California Department of Water Resources (DWR) Basin boundary (DWR No. 3-004.01) as well as areas on the periphery of the boundary (**Figure 1**). The rectangular cells have a variable dimension of 200 feet (ft) up to 675 ft on a side, with the most resolved (200 x 200 ft) grid cells located in the Marina-Ord area where the majority of groundwater extraction and monitoring occurs within the Basin. The coordinates of the lower left corner of the grid are 5,740,227 E., 2,169,843 N. (CA State Plane Zone 4, NAD83, Feet). The grid is rotated 240 degrees counterclockwise so that the columns align approximately with the 180/400-Foot Aquifer Subbasin boundary to the north and the Seaside Subbasin boundary to the south, consistent with the alignment of the Seaside Basin Groundwater Model (*Hydrometrics 2009 & 2019,* see *Section 2.4.2.2*).

The rectangular model grid has been further segmented into an active area (i.e., where groundwater flow is explicitly simulated) and an inactive area (where cells are assigned no-flow boundary conditions). The active area covers the entirety of the Basin as well as the small portion of the 180/400-Foot Aquifer Subbasin south of the Salinas River. The northern boundary of the active grid is the Salinas River, the western boundary is the Pacific Ocean, the southern boundary is the Seaside Subbasin boundary, and the eastern boundary is the Basin edge (i.e., where aquifer sediments come in contact with low permeability bedrock). Transient groundwater conditions along each of the active model boundaries are represented using unique boundary conditions as further described in *Section 2.4*. The number and location of active cells varies by model layer based on previously mapped aquifer extents as further described in *Section 2.2.3*.

2.2.2 Temporal Approach

2.2.2.1 Historical Simulation

The historical simulation is discretized temporally into 240 monthly stress periods, representing a 20-year simulation period from DWR Water Year (WY) 1999 (i.e., October 1998) through WY 2018 (i.e., September 2018). All 20 years of the historical simulation period were used for model calibration as further described in *Section 4*.

GSPs are required to "*provide a quantitative assessment of the historical water budget, starting with the most recently available data and extending back a minimum of 10 years, or as is sufficient to calibrate and reduce the uncertainty of the tools and methods used to estimate and future water budget information and future aquifer response to proposed sustainable groundwater management practices over the planning and implementation horizon*" (23-California Code of Regulations [CCR] §354.18(b)(2)). The historical water budget accounting period is WY 2004 – 2018, which allows for a five-year pre-conditioning period (i.e., WY 1999 – 2003) to minimize the influence of uncertainty in the specified initial conditions.

2.2.2.2 Projected Simulations

Projected water budgets are required "*to estimate future baseline conditions of supply, demand, and aquifer response to Plan implementation*" (23-CCR §354.18(b)(3)). The projected water budget "*must use 50 years of historical precipitation, evapotranspiration (ET), and streamflow information as the basis for evaluating future conditions under baseline and climate-modified scenarios"* (23-CCR §354.18(e)(2)(A)).

Several projected scenarios were developed from the historical model to evaluate aquifer response to future climate, land use, and water supply and demand conditions (See GSP *Section 6.5 Projected Water Budget* for further details). To develop the required 50 years-worth of hydrologic input information, first an "analog period" was created from the 20 years of historical information (WY 1999-2018) by combining the years in a specific way that, on average, maintained the long-term average hydrologic conditions. This approach allowed for the creation of a complete 50-year period to inform the projected water budget analysis, even when certain component datasets were not available for that length of time. The sequence of historical years that were combined to create the 50-year analog period is as follows:

- Analog Years 1-20: Based on historical years 1999-2018
- Analog Years 21-40: Based on historical years 1999-2018
- Analog Years: 41-50: Based on historical years 1999-2008

The above mapping of historical years to analog years within the required 50-year projected water budget period applies to precipitation and ET datasets.

The projected simulations are discretized temporally into 600 monthly stress periods, representing a simulated analog period from WY 2019 (i.e., October 2018) through WY 2068 (i.e., September 2068). This 50-year simulation was used to develop projected water budget estimates and to evaluate the benefits of proposed projects and management actions over the 50-year planning and implementation period following GSP submittal.

2.2.3 Vertical Geometry

The model is discretized vertically into eight layers as described below:

- **Layer 1** represents Dune Sand Aquifer;
- **Layer 2** represents the Fort Ord/Salinas Valley Aquitard;
- **Layer 3** represents the Upper 180-Foot Aquifer;
- **Layer 4** represents the 180-Foot Aquitard;
- **Layer 5** represents the Lower 180-Foot Aquifer;
- **Layer 6** represents the 180/400-Foot Aquitard;
- **Layer 7** represents the 400-Foot Aquifer; and
- **Layer 8** represents the Deep Aquifer / El Toro Primary Aquifer[1]

[1] The El Toro Primary Aquifer is defined as the only Principal Aquifer unit within the Corral de Tierra Management Area and is generally consistent in hydrogeology to the lower 400-Foot and Deep Aquifers within the Main Basin. See GSP *Section 4.2.2.* for further details.

Each layer of the MBGWFM represents a unique Principal Aquifer or Aquitard unit defined in the GSP and is consistent with previous hydrogeologic conceptualizations of the Basin. A more detailed description of the hydrogeology, geometry, and current groundwater conditions of each Principal Aquifer and Aquitard unit within the Basin is provided in *Sections 4 and 5* of the GSP. A summary table of the geologic-hydrogeologic relationships of each Principal Aquifer and Aquitard unit is provided in **Table 1** below:

Table 1. Generalized Geologic – Hydrogeologic Relationships

<table>
<tr><th>Period/Epoch</th><th>Geological Unit</th><th>Principal Aquifers and Aquitards</th></tr>

</table>

Notes:

(1) The 180-Foot Aquifer is separated into “upper” and “lower” zones, separated by a thin clay layer known as the “180-Foot Aquitard”. Data collected within the former Fort Ord show that significant head differences exist between the upper and lower zones of the 180-Foot Aquifer.

(2) The presence and extent of the “400-Foot/Deep Aquitard” is not well understood within the Monterey Subbasin and thus is not represented by a unique layer in the MBGWFM. The Deep Aquifer (MGWFM Layer 8) has been parameterized to reflect zones of low vertical hydraulic conductivity where this aquitard is presumed to exist in the subbasin (see Section 2.5.1 for further details).

As described in detail in GSP *Sections 4 and 5*, Principal Aquifer units within the Basin have varied spatial extent, thickness, and degrees of confinement. As part of GSP development, a three-dimensional (3D) hydrostratigraphy model of the Basin was prepared using the Leapfrog Geo[2] geologic modeling software program to provide for a more accurate representation of Principal Aquifer and Aquitard geometries and to facilitate MBGWFM grid development. The Leapfrog hydrostratigraphy model of the Basin was originally developed as part of two Airborne Electromagenetic (AEM) geophysical surveys conducted by Marina Coast Water District (MCWD) in 2017 and 2019 (*Stanford/Aqua Geo Frameworks, 2017; Aqua Geo Frameworks, 2019*) to help characterize seawater intrusion within the Basin. The Leapfrog hydrostratigraphy model was revisited and modified by EKI in 2020 to incorporate additional lithologic and hydrostratigraphy data from various well and borehole logs and well as several cross-sections previously developed for the Basin (*Harding ESE, 2001; GeoSyntec, 2007; GeoSyntec, 2010*). The updated Leapfrog hydrostratigraphy model was used as the basis to inform the spatial extents, elevations, and thicknesses of each layer within the MBGWFM. **Figure 2** shows a representative cross-section of the Marina-Ord area of the Basin derived from the Leapfrog hydrostratigraphy model and corresponding MBGWFM layers.

One limitation of the Leapfrog hydrostratigraphy model is that it does not extend into the southern portion of the Corral de Tierra Management Area on the southeastern side of the Basin. Within the southern Corral de Tierra area, aquifers have historically been described by their geologic names, such as the Aromas Sand, Paso Robles Formation, and Santa Margarita Sandstone (*Geosyntec, 2007; Yates 2005*). Based on best available information, these geologic formations are grouped together to form the "El Toro Primary Aquifer System" for the Corral de Tierra Area as described in further detail in GSP *Section 4*. These geologic formations also comprise the lower portions of the 400-Foot Aquifer and the Deep Aquifers in the northern Salinas Valley including the Marina-Ord Area. As such, the El Toro Primary Aquifer was represented using model Layer 8, which is the only active model layer within the Corral de Tierra Management Area (see **Figure 3**).

Another limitation of the Leapfrog hydrostratigraphy model is that it does not effectively map the bottom of the Basin, which is defined as the top of the Monterey Formation (see GSP *Section 4*). As such, the bottom of MBGWFM Layer 8 (Deep Aquifer / El Toro Primary Aquifer) was delineated in the MBGWFM using a surface representing the Top of Monterey Formation Elevations previously developed by the Seaside Basin Watermaster (see GSP *Figure 4-3*).

Figure 3 shows the active extents of each layer within the MBGWFM and the uppermost active Principal Aquifer units encountered across the model domain. **Figure 4** and **Figure 5** show the top elevations of each model layer, while **Figure 6** and **Figure 7** show the layer thicknesses. These figures demonstrate that the MBGWFM reasonably represents the geometry and extent of each Principal Aquifer unit defined within the Basin as described in detail in *Section 4* of the GSP.

As described in *Section 5* of the GSP, each Principal Aquifer unit may experience varied degrees of confinement depending on location within the Basin, presence of overlying aquitard units, and current groundwater level conditions. As such, each layer was assigned a "convertible" layer type in the Upstream Weighting Package (UPW) of the MODFLOW-NWT program to allow for continued transition between confined and unconfined conditions throughout the model simulation depending on transient groundwater head conditions. Similarly, as mentioned in *Section 2.1,* the Newton formulation version of MODFLOW-2005 (MODFLOW-NWT) was employed for the MBGWFM because it allows for rewetting of cells (i.e., keeping them active as opposed to deactivating them) in the event the water table drops below the bottom elevation of a given cell at any point during the transient simulation.

[2] https://www.seequent.com/products-solutions/leapfrog-geo/

Finally, there are areas of the Basin where certain aquifer or aquitard units pinch out to zero thickness and terminate, resulting in direct connectivity between non-sequential aquifer units. An example of this is the Fort Ord/Salinas Valley Aquitard (Layer 2), which only exists in a portion of the Marina-Ord Area. Where the aquitard is not present, the Dune Sand Aquifer (Layer 1) is in direct contact with the Upper 180-Foot Aquifer (Layer 3). Pinch-out geometries are challenging to accurately represent in MODFLOW-NWT because cells with zero thickness and inactivated cells will act as no-flow boundaries and prevent vertical hydraulic connection between overlying and underlying model layers. A minimum cell thickness of five feet was applied to model cells in these pinch-out areas to allow for continued hydraulic connectivity between non-sequential model layers. As described further in *Section 2.5,* these cells were assigned the same aquifer parameters as the nearest overlying active model layer such that they essentially act as "flow-through" cells allowing vertical groundwater flow between non-sequential model layers. The location of these "flow-through" cells are shown by layer on **Figure 6** and **Figure 7.**

2.3 Initial Conditions

2.3.1 Historical Simulation

The availability and density of historical groundwater elevation data varies substantially throughout the Basin, both spatially and temporally. While the Monterey County Water Resources Association (MCWRA) maintains a database of water level records throughout the entire Salinas Valley Groundwater Basin, available records before WY 1999 were generally limited to the Marina-Ord Management Area of the Basin. As such, initial heads in the MBGWFM were derived from Fall 1998 water level data wherever available and supplemented with historical water level contour maps previously created for the Corral de Tierra Management Area to provide for complete coverage of the Basin.

Fall 1998[3] water levels were compiled from MCRWA records for 362 wells within the Basin and in the surrounding Seaside and 180/400-Foot Aquifer Subbasins and used to create preliminary surfaces (i.e., rasters) of initial heads for the MBGWFM historical simulation. Initial head rasters were created in Surfer using the Kriging interpolation method, whereby a Gaussian model variogram was fitted to the water level datasets and applied to create rasters of Fall 1998 water levels for each Principal Aquifer unit.

As mentioned previously, initial heads in the Corral de Tierra Management Area were also informed by contoured water level maps previously created by Geosyntec Consultants as part of the El Toro Groundwater Study (*Geosyntec, 2007*). Specifically, a contour map of January 2001 groundwater elevations (Figure 4-5 of *Geosyntec, 2007*) was digitized (i.e., converted into a series of point elevations) and subsequently used to refine and extend the initial head rasters so that they covered the entirety of the Basin.

Groundwater elevations were subsequently extracted from the initial head rasters at every active grid cell for each aquifer layer of the MBGWFM (i.e., layers 1, 3, 5, 7, and 8) to populate the initial head arrays in the Basic (BAS) package of MODFLOW-NWT. Initial heads were assigned to the aquitard layers (i.e., layers 2, 4, and 6) using water level surfaces from the overlying aquifer unit where applicable.

[3] Seasonal average water levels were calculated for each well, where Fall includes measurements from August 15th to November 15th and Spring includes measurements from January 15th to April 15th.

2.3.1 Projected Simulations

Initial heads for all projected simulations in the MBGWFM were defined using the final head outputs from the historical simulation (i.e., simulated heads from September 30, 2018).

2.4 Boundary Conditions

Boundary conditions represent flow constraints in the model domain. Three types of boundary conditions are specified in the MBGWFM: 1) no-flow boundary, 2) general-head boundary, and 3) river boundary. Each of these boundary conditions are discussed in greater detail below. A schematic summarizing all boundary conditions employed in the model is presented in **Figure 8**.

2.4.1 No-Flow Boundary

A no-flow boundary is employed wherever groundwater flow is assumed to be zero within a cell, effectively removing it from the groundwater flow simulation. No-flow boundaries are commonly used to represent contacts with impermeable (non-water bearing) formations or to inactivate a portion of the model grid that is outside the study area. The following areas are represented as no-flow boundaries within the MBGWFM:

- The eastern Basin boundary, where aquifer sediments of the El Toro Primary Aquifer (Layer 8) come in contact with impermeable bedrock outcrops;
- The model bottom, which coincides with the top of the Monterey Formation (i.e. bedrock); and
- The western Basin boundary within the Deep Aquifer (Layer 8), as it is assumed the Deep Aquifer is not hydraulically connected to the Pacific Ocean (see *Section 2.4.2.3*).

All other cells outside the active model area are also assigned as no-flow cells such that they are excluded from the MODFLOW simulation.

2.4.2 General-Head Boundary

The general-head boundary (GHB) is a head-dependent flow boundary, and the flow across this boundary is proportional to the difference between the model-calculated head at the boundary and a general head located a certain distance from the boundary. The proportionality constant used to calculate the flow is the conductance, which is calculated from the hydraulic conductivity of the boundary cell, the area of the face of the boundary cell, and the distance from the boundary cell to the general head location.

As described in more detail in GSP *Sections 4 and* 5, the northern, southern, and western boundaries of the Basin are hydraulically connected to aquifer units of the 180/400-Foot Aquifer Subbasin, Seaside Subbasin, and the Pacific Ocean, respectively. As such, the northern, southern, and western boundaries of the active model domain are represented by GHBs[4].

The general process for developing GHBs in the MBGWFM was to: (1) identify GHB cells for each active model layer, (2) gather transient general head data from nearby locations to the GHB cells outside the

[4]Two exceptions to this are: (1) the northern boundary of Layers 1 and 2, where the Salinas River is directly simulated using a River boundary (see *Section 2.4.3*), and (2) the western boundary of Layer 8, which is represented as a no-flow boundary because is assumed the Deep Aquifer is not hydraulically connected to the Pacific Ocean.

active model domain, (3) calculate distances and associate GHB cells with their nearest general head location, and (4) assign transient general heads and conductance properties to each GHB cell[5]. The methods and datasets used to develop GHBs at each boundary are further described below.

2.4.2.1 *Northern Boundary (Salinas River / 180-400-Foot Aquifer Subbasin)*

As mentioned in *Section 2.2.1,* the active model area extends north of the Basin boundary up to the Salinas River, thus including a small portion of the 180/400-Foot Aquifer Subbasin. While the Salinas River is explicitly simulated in MBGWFM layers 1 and 2 (see *Section 2.4.3*), the northern boundary in underlying layers (i.e., layers 3-8) is represented by GHBs in the model to simulate groundwater exchanges between the Monterey Subbasin the neighboring 180/400-Foot Aquifer Subbasin.

2.4.2.1.1 Historical Simulation

Transient general heads were assigned to northern boundary GHB cells using historical groundwater elevation monitoring data provided by MCWRA. Groundwater elevation measurements from the historical simulation period (i.e., October 1999 – September 2018) were compiled from all monitoring wells to the immediate north of the Salinas River and examined for quality. A subset of these wells were ultimately selected as “representative” monitoring wells to assign transient general heads at GHB cells along the northern boundary for model layers 3–8. The selection of representative wells to use for GHB parameterization was informed by the availability, frequency, and quality of historical monitoring data as well as the location and distribution of wells along the northern boundary.

The final network of representative monitoring wells includes seven wells in the Upper 180-Foot Aquifer (Layer 3), 12 wells in the Lower 180/400-Foot Aquifer (Layers 5 and 7)[6], and three wells in the Deep Aquifer (Layer 8). Each active GHB cell in model layers 3–8 was associated to the nearest representative well[7] and the distance between the GHB cell and its associated representative well was calculated to inform the GHB conductance term. GHB cells along the northern model boundary and their associated representative monitoring wells are shown for each model layer in **Figure 9.**

Historical groundwater elevation data from each representative monitoring well was pre-processed to create a continuous monthly timeseries of general heads to assign to its associated GHB cells. Where multiple records existed for a well within a given month, an average groundwater elevation was calculated for that month. Where data was unavailable at a well for a particular month, the monthly water level was either estimated via (Pearson) correlation[8] to nearby monitoring wells with data for that month or, when

[5] GHB conductance parameters were adjusted during calibration as described in *Section 4.3*.

[6] Along most of the northern MBGWFM boundary, the 180-Foot Aquitard is present while the 180/400-Foot Aquitard is absent (see **Figures 6 and 7**). Historical water level observations collected in this area indicate that groundwater elevations within the Lower 180-Foot Aquifer closely resemble water levels in the 400-Foot Aquifer along the northern basin boundary. Furthermore, water level contour maps for the Lower 180-Foot Aquifer created by EKI closely resemble MCWRA contour maps of the 400-Foot Aquifer along the boundary. As such, northern GHB heads were assigned to MBGWFM Layers 5 and 7 using water levels collected from MCWRA wells characterized in the “180/400-Foot Aquifer.”

[7] Specified heads were assigned to GHB cells in aquitard units (i.e., model layers 4 and 6) using water level data from representative wells in the overlying aquifer unit (i.e., model layers 3 and 5, respectively).

[8] A linear regression (Pearson) correlation matrix was developed for all representative wells within a Principal Aquifer unit to identify “well-correlated” wells for use in data-gap filling. A correlation coefficient (R) threshold of $R \geq 0.8$ was used to determine if wells were well-correlated and thus suitable for use in estimating missing water level data. The final linear regression equations used to estimate missing water level records were derived from the nearby well with the highest R value (where $R \geq 0.8$) to the representative well in question.

no well-correlated data was available, via linear interpolation between measurements at the well. The final (post-processed) monthly water level datasets from each representative monitoring well were subsequently used to assign transient general heads at all associated GHB cells throughout the historical model simulation period.

2.4.2.1.2 Projected Simulations

The same approach described above was used to set up the northern boundary GHB in the projected simulations, except now the general heads were informed by groundwater elevation Sustainability Criteria defined in the 180/400-Foot Aquifer Subbasin GSP ("180/400 GSP", *SVBGSA, 2020)* as opposed to historical monitoring data. Specifically, the "representative" monitoring well network used to inform historical general heads at nearby GHB cells was updated to include all SGMA monitoring network wells located immediately north of the Salinas River in the 180/400-Foot Aquifer Subbasin. In many cases, these SGMA monitoring wells were the same representative wells employed in the historical simulation.

The final network of SGMA monitoring wells used for projected simulations includes seven wells in the Upper 180-Foot Aquifer (Layer 3), 10 wells in the Lower 180/400-Foot Aquifer (Layers 5 and 7), and three wells in the Deep Aquifer (Layer 8). Each active GHB cell in model layers 3–8 was reassociated to the nearest SGMA monitoring well[9] and assigned a GHB conductance term from the calibrated historical model. GHB cells along the northern model boundary and their associated SGMA monitoring wells are shown for each model layer in **Figure 10.**

Depending on the projected scenario, GHB cells were then assigned general heads based on one of the following three ranges in future groundwater level conditions that could be encountered at the 180/400-Foot Aquifer Subbasin while maintaining SGMA compliance:

- **"Minimum Threshold" (MT)** water levels (as defined in the 180/400 GSP)
- **"Measurable Objective" (MO)** water levels (as defined in the 180/400 GSP)
- **"Seawater Intrusion (SWI) Protective"** water levels (see *Section 2.4.2.3* for further details).

For all projected scenarios, initial general heads at the GHB cells were informed by final head outputs from the historical simulation (i.e., simulated heads from September 30, 2018)[10]. General heads were then adjusted using a 20-year "ramp up" period to reach the projected water level conditions described above. For the "MT" and "SWI Protective" water level scenarios, the ramp up period was applied linearly over 20 years. For the "MO" water level scenario, the ramp up period was informed by five-year interim milestones defined at each SGMA monitoring well in the 180/400 GSP. All projected water levels at the GHB cells were then held constant for the remaining 30 years of the projected simulations, under the assumption that these water levels would be maintained in perpetuity after the 20-year SGMA implementation deadline.

[9] *Ibid [6].*

[10] Review of historical groundwater level data indicates that September water levels represent a reasonable annual average condition (i.e., between seasonal high and low conditions) within the 180/400-Foot Aquifer subbasin and are thus appropriate to use as a starting point for developing projected heads at the northern GHB boundary.

2.4.2.2 Southern Boundary (Seaside Subbasin)

As mentioned in *Section 2.2.1,* the southern boundary of the active model area is aligned with the Seaside Subbasin boundary. This boundary was represented as a GHB in the MBGWFM to simulate groundwater exchanges between the Monterey Subbasin the neighboring Seaside Subbasin.

2.4.2.2.1 Historical Simulation

Transient general heads were assigned for southern boundary GHB cells in the MBGWFM historical simulation using head outputs from the Seaside Basin Groundwater Model ("Seaside Model") (*Hydrometrics, 2009 & 2019*). The Seaside Model simulates groundwater flow within the Seaside Subbasin from January 1987 – January 2018 and extends partially into the Monterey Subbasin. A copy of the Seaside Model was provided to EKI by the Seaside Basin Watermaster in early 2020 to facilitate direct incorporation of simulated head outputs from the Seaside Model along the Basin boundary into the MBGWFM.

EKI extracted simulated head outputs from the Seaside Model at a series of 20 regularly spaced "proxy" monitoring locations distributed along the south side of the Seaside boundary. Each active GHB cell along the Seaside boundary in the MBGWFM was subsequently associated to its nearest proxy monitoring location, and transient general heads were assigned to the GHB cells using the monthly simulated head outputs from the Seaside Model at their respective proxy monitoring locations[11]. GHB cells along the Seaside boundary and their associated proxy monitoring locations are shown in **Figure 11.**

While employing the Seaside Model to develop Seaside boundary GHBs in the MBGWFM provides for a common set of assumptions regarding historical heads along the boundary, there are notable differences in hydrogeologic conceptualization and geometry between the two models that will result in imperfect matching of head conditions and unique estimates of cross-boundary flows. Notably, the Seaside Model defines aquifer units differently than the MBGWFM and includes a different number of layers. The Seaside Model is comprised of five layers that represent the following aquifer units (*Hydrometrics, 2009*):

- Layer 1 represents the Older Dune deposits and Aromas Red Sands
- Layer 2 represents the upper Paso Robles Aquifer
- Layer 3 represents the "brown sand layer" of the lower Paso Robles Aquifer
- Layer 4 represents the "semi-continuous blue clays" encountered at the base of the Paso Robles Aquifer
- Layer 5 represents the Santa Margarita/Purisima Aquifer

As demonstrated in **Table 1** (see *Section 2.2.3*), these aquifer units are generally defined based on the geologic formations encountered in the region and are only loosely tied to the Principal Aquifer Units defined in the Monterey Subbasin. For example, Older Dune deposits and Aromas Red Sands deposits (Seaside Model layer 1) have been further stratified into the Dune Sand Aquifer (Layer 1), Upper 180-Foot Aquifer (Layer 3), Lower 180-Foot Aquifer (Layer 5), and 400-Foot Aquifer (Layer 7) in the MBGWFM. Previous hydrogeologic investigations (see *GSP Section 4*) indicate that the 400-Foot Aquifer is likely comprised of both Aromas Sands (Seaside Model layer 1) as well as upper portions of the Paso Robles

[11] As the Seaside Model historical simulation period ends in January 2018, simulated head outputs were estimated in the MBGWFM for Feb. 2018 – Sept. 2018 using Seaside Model head outputs for Feb. 2017 – Sept. 2017.

formation (Seaside Model layer 2) depending on location within the Monterey Subbasin. Similarly, the Deep Aquifer (Layer 8) of MBGWFM represents the combined lower Paso Robles (Seaside Model layers 3-4) and Santa Margarita / Purisima (Seaside Model layer 5) formations.

Given the imperfect match in conceptualization and layering between the two models, a few simplifying assumptions were needed to effectively link head outputs from the Seaside model to GHB cells along with southern boundary of the MBGWFM. Ultimately, the selection of which Seaside Model layers should be associated to GHB cells in the MBGWFM was informed by: (1) a comparison of Seaside Model head outputs along the boundary with recent (i.e., Spring and Fall 2017) contour maps of each Principal Aquifer Unit in the Monterey Subbasin; and (2) an iterative evaluation of water budget and simulated head outputs from MBGWFM to ensure cross-boundary flow estimates generally agreed with Seaside Model outputs, both in magnitude and in spatial trends. The final mapping of MBGWFM GHB cells to their corresponding Seaside Model layers is presented in **Table 2** below:

Table 2. Mapping of Seaside Model Layers to MBGWFM GHB Cells at the Seaside Boundary

MBGWFM GHB Layer	MBGWFM Principal Aquifer Unit	Seaside Model Layer	Seaside Model Aquifer Unit
1	Dune Sand Aquifer	1	Older Dune deposits and Aromas Red Sands
3	Upper 180-Foot Aquifer	1	Older Dune deposits and Aromas Red Sands
5	Lower 180-Foot Aquifer	1	Older Dune deposits and Aromas Red Sands
7	400-Foot Aquifer	2	Upper Paso Robles Aquifer
8	Deep Aquifer / El Toro Primary Aquifer	3 (Proxy Points 1-9)	Lower Paso Robles Aquifer
		4 (Proxy Point 10)[(1)]	Paso Robles Base (Blue Clays)
		5 (Proxy Points 11-20)[(2)]	Santa Margarita / Purisima Aquifer

<u>**Notes:**</u>

(1) Seaside Model layer 3 becomes dry moving east of proxy point 9 along the boundary, and thus the uppermost active unit is layer 4.

(2) Seaside Model layer 4 is either dry or constrained by dry cells and shows erroneously high-water levels (i.e., >200 feet above ground surface) moving east of proxy point 10. Thus, the only reliable layer to use east of proxy point 10 becomes layer 5.

Annual net cross-boundary flow estimates from the Seaside Model and the calibrated MBGWFM over the historical water budget period[12] are compared on **Figure 12.** Over like timeframes, the Seaside Model estimates an average net inflow from the Seaside Subbasin to the Monterey Subbasin of +935 acre-feet per year (AFY) while the MBGWFM estimates an average net inflow of +918 AFY. These results indicate that the calibrated MBGWFM reasonably recreates historical groundwater level conditions simulated by Seaside Model along the boundary and that resulting water budget estimates of historical cross-boundary flows between the two models are in very close agreement at the Basin-level. Further refinements could bring the historical models into closer agreement.

2.4.2.2.2 Projected Simulations

Unlike the 180/400-Foot Aquifer Subbasin, the Seaside Subbasin is an adjudicated groundwater basin and is not subject to many aspects of SGMA. As such, no Sustainability Criteria have been defined for groundwater elevations within the Seaside Subbasin, as the basin is required to manage to a groundwater budget as opposed to groundwater elevations. The adjudication also states that management of the Seaside Basin cannot result in "material injury" to the Basin, which could include low groundwater elevations that impact production rates.

For the projected simulations, a simplifying assumption was made that the Seaside Subbasin would be able to maintain Fall 2017 water levels over the long term, thus managing to a balanced water budget (i.e., no long-term depletion of groundwater storage). As such, September 2017 water level outputs from the Seaside Model were used to define reference heads along the southern GHB boundary for all MBGWFM projected simulations throughout the entire 50-year simulation period.

One exception to the assumption described above is along the southeastern edge of the Seaside-Monterey boundary (i.e., near Laguna Seca). In this area, simulated Fall 2017 water levels from the Seaside Model were already below the Minimum Thresholds (MTs) defined for wells in the Corral de Tierra Management Area on the Monterey Subbasin side of the boundary (i.e., 170 feet above mean sea level [ft msl], see GSP *Sections 7 and 8*). Projected GHB reference heads were set at the minimum threshold of 170 ft msl in the MBGWFM for all GHB cells in the Laguna Seca area whose simulated water levels were below 170 ft msl in the Seaside Model as of September 2017. This assumption was considered reasonable because Cal-Am ceased all its municipal pumping from the Laguna Seca area in 2021, reducing total pumping in that area by approximately 30%. While the effect of this pumping reduction is still to be established, it is likely that pumping in the Laguna Seca will not be the driver of lower groundwater levels. This adjustment was ultimately made to all GHB cells associated with "proxy" monitoring points 14 and 15 along the Seaside boundary (see **Figure 11**).

It is recognized that there is considerable uncertainty regarding future groundwater conditions within the Seaside Subbasin (particularly within the Laguna Seca area) and that groundwater management decisions in the Monterey Subbasin are likely to impact groundwater conditions within the Seaside Subbasin, and vice-a-versa. Various studies and projects have been proposed (see *GSP Section 9*) or are already being implemented by water management entities in both subbasins to better characterize and model local groundwater conditions and cross-boundary flows in the Laguna Seca area and across the entire Monterey-Seaside boundary. As more data and information is

[12] WY 2018 is excluded from the comparison as the Seaside Model only simulates historical groundwater conditions through January 2018

developed in the coming years, the MBGWFM will be revised and updated accordingly as part of the next five-year update to the GSP.

2.4.2.3 *Western Boundary (Pacific Ocean)*

As mentioned in *Section 2.2.1,* the western boundary of the active model area is aligned with the Pacific Ocean. This boundary was represented as a GHB in the MBGWFM to simulate exchanges between the Basin and the ocean and to inform estimates of potential seawater intrusion rates into the Basin.

The current version of the MBGWFM does not directly simulate variable-density groundwater flow and transport. Instead, the Pacific Ocean boundary is represented as a GHB using freshwater equivalent sea levels calculated at the aquifer-seafloor interface for each Principal Aquifer unit assumed to be in hydraulic connection with the ocean.

Freshwater equivalent sea levels are calculated based on the equivalent freshwater head formula for variable density groundwater flow presented in the USGS *User's Guide to SEAWAT* (*Guo and Langevin, 2002*), which states:

$$h_{fw} = \frac{\rho}{\rho_f} h - \frac{\rho - \rho_f}{\rho_f} Z$$

where h_{fw} = freshwater equivalent head, h = sea level, ρ = saline water density, ρ_f = freshwater density, and Z = elevation of measuring point. In this instance, since the equivalent freshwater head is being calculated at the (offshore) ocean-aquifer interface, Z represents the depth to the seafloor at the estimated seafloor-aquifer contact location.

Previous hydrogeologic investigations along the Monterey coastline indicate that the Recent and Older Dune Deposits, Aromas Red Sands, and Paso Robles Formations are at least partially in contact with the seafloor at varying distances offshore from the Basin, while the deeper Santa Margarita and Purisima Formations may be hydraulically restricted from the sea floor by the Monterey Bay Fault Zone (*Feeney, 2003).* More recent investigations of seawater intrusion conditions within the Basin (*Aqua Geo Frameworks, 2019,* see GSP *Section 5*) also indicate that the Deep Aquifer is not currently seawater intruded along the Monterey coastline. As such, GHB cells were assigned along the Pacific Ocean boundary for all layers in the MBGWFM apart from layer 8 (i.e., the Deep Aquifer), which was modeled as a no-flow boundary at the Monterey coastline.

2.4.2.3.1 Historical Simulation

For the historical simulation, freshwater equivalent sea levels were calculated for each model layer using the *Guo & Langevin, 2002* equation described above at a sea level elevation (*h*) of zero (0) ft msl and a saline water density of 1.025 grams per cubic centimeter (g/cm^3). Average elevations (i.e., depths below sea level) at which each Principal Aquifer unit are assumed to contact the seafloor were estimated using a previously developed geologic cross-section of the Monterey Bay coastal aquifer system (see Figure 5 of *Feeney, 2003*). Corresponding offshore distances to the assumed point of contact with the seafloor were then calculated at each GHB cell using a bathymetry map of seafloor elevations and used to inform conductance term at each cell. **Table 3** below presents a summary of freshwater heads assigned to each model layer for the historical simulation.

Table 3. Freshwater Equivalent Sea Levels – Historical Simulation

MBGWFM GHB Layer	Corresponding Geologic Formation from *Feeney, 2003*	Average Offshore Distance to Seafloor Contact (ft)	Average Elevation of Seafloor – Aquifer Contact (ft msl)	Calculated Freshwater Equivalent Head (ft msl)
1 – 6	Recent / Older Dune Deposits	9,000	-155	3.8
7	Aromas Red Sands / Paso Robles	26,800	-335	8.4

Calculated freshwater heads were held constant in Pacific Ocean GHB cells throughout the historical simulation under the assumption that the sea level did not change significantly between WY 1999 – 2018.

2.4.2.3.2 Projected Simulations

As further described in *Section 3.1*, three climate change scenarios were modeled in the MBGWFM projected simulations. Each of these scenarios employed unique assumptions regarding future sea level rise that were derived from the 180/400 GSP (*SVBGSA, 2020*). These included:

- **Baseline Conditions** – assumes no change in sea level (0 ft msl)
- **2030 Climate Change –** assumes a "moderate" increase in sea levels of 15 cm (+ 0.492 ft msl)
- **2070 Climate Change** – assumes a "severe" increase in sea levels of 45 cm (+ 1.475 ft msl)

Freshwater equivalent ocean heads were recalculated under each projected scenario using the same assumptions about offshore contact depths and distances employed in the historical simulation (see **Table 3** above). **Table 4** below presents a summary of freshwater heads assigned to Pacific Ocean GHB cells for each model layer under the various projected scenarios.

Table 4. Freshwater Equivalent Sea Levels – Projected Simulations

MBGWFM GHB Layer	"Baseline" Freshwater Equivalent Head (ft msl)	"2030 Climate Change" Freshwater Equivalent Head (ft msl)	"2070 Climate Change" Freshwater Equivalent Head (ft msl)
1 – 6	3.8	4.3	5.4
7	8.4	8.9	9.9

Calculated freshwater heads were held constant in Pacific Ocean GHB cells throughout each of the 50-year projected simulations.

As described in *Section 2.4.2.1.2*, projected simulations along the northern GHB boundary included a "Seawater Intrusion (SWI) Protective" water level scenario to estimate potential cross-boundary flows assuming the 180/400-Foot Aquifer Subbasin is able to maintain freshwater equivalent sea levels along the entire length of the 180/400-Monterey boundary. For this scenario, GHB cells along the northern boundary were assigned specified heads using the freshwater equivalent sea levels calculated under each climate scenario shown in **Table 4**. Consistent with the MT and MO scenarios, GHB cells along the northern boundary were allowed a 20-year "ramp up" period starting from their Fall 2018 heads to reach these SWI Protective water levels and were then held constant for the remaining 30 years of the projected simulation period.

2.4.3 River Boundary

The Salinas River was explicitly simulated in model layers 1 and 2 at the MBGWFM northern boundary using MODFLOW's River (RIV) package[13] (**Figure 9**). The RIV package is used to simulate head-dependent flux boundaries between a river and the underlying groundwater system.

RIV cells were identified in the MBGWFM using a shapefile of the Salinas River obtained from the National Hydrography Dataset (NHD). River segment lengths were calculated at each model cell from the NHD shapefile, and land surface elevations were estimated using a 30-meter USGS National Elevation Dataset (NED) raster. Streambed widths were assigned to each RIV cell using data obtained from the North Marina Groundwater Model (NMGWM) (*Hydrofocus, 2017)*. A streambed thickness of five (5) feet was assigned to each RIV cell consistent with the NMGWM and the Salinas Valley Integrated Ground and Surface Water Model (SVIGSM)[14] (MCWRA & *LSCE, 2006*), and river bottom elevations were calculated as the land surface elevation minus the streambed thickness. Riverbed conductance values were initially assigned to each RIV cell using parameters obtained from the NMGWM and were subsequently adjusted during model calibration (see *Section 0*).

2.4.3.1 Historical Simulation

For the historical simulation, river stages were assigned to each RIV cell using historical streamflow monitoring data obtained from the USGS Spreckels Gauge (Site No. 11152500)[15]. The Spreckels Gauge is conveniently located in the active MBGWFM domain at model cell [40,85] and thus serves as a reasonable proxy for estimating Salinas River stages along the length of the northern model boundary.

The Spreckels Gauge provides monthly discharge rates within the river and a series of field measurements that contain both stage and flow data at the monitoring station. These field measurements were used to develop a streamflow rating curve for the site, which was subsequently applied to estimate river stages at the Spreckels Gauge location from monthly discharge data for October 1998 – September 2018 (**Figure 13).** River stage elevations were subsequently assigned to each RIV cell upstream and downstream of the Spreckels Gauge location using differences in land surface elevations as an adjustment factor.

[13] A small number of RIV cells were also assigned to model layer 7 at the northeastern Basin boundary, where layer 7 is the uppermost active model unit (**Figure 9**).

[14] The SVIGSM was recently updated to the Salinas Valley Integrated Hydrologic Model (SVIHM) by the USGS, with preliminary outputs released to the public in mid-2021. The SVIHM was not available for use at the time of MBGWFM construction.

[15] https://waterdata.usgs.gov/nwis/uv?site_no=11152500

2.4.3.2 Projected Simulations

At the time of MBGWFM construction, no information was readily available to assign projected Salinas River flow conditions under future baseline or climate change conditions. As such, a simplifying assumption was made that Salinas River stages would mimic historical trends depending on water year type. Transient RIV stages were therefore estimated for all projected scenarios using historical stages calculated for the 50-year "analog" hydrologic period described in *Section 2.2.2.2*, where:

- Analog Years 1-20: Based on historical years 1999-2018
- Analog Years 21-40: Based on historical years 1999-2018
- Analog Years: 41-50: Based on historical years 1999-2008

2.5 Aquifer Properties

Aquifer properties were initialized in the MBGWFM using available pumping test data and relevant information from prior hydrogeological studies and were subsequently refined during model calibration (see *Section 4.3*). A summary of the initial model parameterization process for hydraulic conductivity and storage properties is provided below.

2.5.1 Hydraulic Conductivity

In alluvial aquifers, the spatial distribution of hydraulic conductivity is influenced by the distribution of sediment texture (i.e., the fraction of coarse-grained sand and gravel relative to the fraction of fine-grained silt and clay), the size and shape of the pores between the sediment grains, and the effectiveness of the interconnections between those pores. To better represent the spatial distribution in hydraulic conductivities within each Principal Aquifer unit, texture maps were constructed for each aquifer layer of the MBGWFM (i.e., layers 1, 3, 5, 7, and 8) based on lithologic descriptions from 332 boreholes distributed throughout the model domain[16]. The final texture maps assigned to each layer are shown on **Figure 14 through Figure 18**.

The texture maps are based on the lithologic descriptions from borehole logs. The borehore logs vary in depth and may be used to assign texture classifications to multiple layers. Layer 1 utilized 145 borehole logs, layer 3 utilized 212 borehole logs, layer 5 utilized 65 borehole logs, layer 7 utilized 178 borehole logs, and layer 8 utilized 144 borehole logs. The logs were coded on a 1-ft interval as either coarse-grained or fine-grained material, using a rubric consistent with the USGS' Central Valley Hydrologic Model (CVHM; *Faunt et al., 2009*). For each borehole, the average fraction of coarse-grained sediment was calculated over the total thickness of each model layer at the borehole location. Resultant values were interpolated in Surfer using the Kriging interpolation method to create rasters of coarse-grained fractions for each aquifer layer and were subsequently assigned to each active model cell by layer (**Figure 14 through Figure 18**). In general, the borehole data indicate that layer 1 has the greatest fraction of coarse-grained sediment, and the sediments generally become finer with depth.

Areas and depth intervals characterized with relatively coarse-grained sediments transmit water at a higher rate than areas and depth intervals characterized by fine-grained sediments. The resulting distributions in the fraction of coarse-grained sediment was therefore utilized to specify the spatial

[16] Texture maps were not created for the aquitard layers of the model (i.e., layers 2, 4, and 6) as it is assumed they are predominantly fine-grained in nature. Final hydraulic conductivities assigned to aquitard units were determined through model calibration as further discussed in *Section 4.2*.

distribution in horizontal and vertical hydraulic conductivity. The modeled horizontal hydraulic conductivity is calculated as the product of the fraction of coarse-grained sediment and specified coarse-grained horizontal hydraulic conductivity. Vertical hydraulic conductivity is typically less than horizontal hydraulic conductivity because fine-grained beds can impede the downward movement of water. The modeled vertical hydraulic conductivity is therefore calculated as the specified vertical hydraulic conductivity divided by the fraction of fine-grained sediment, where the fine-grained fraction is calculated as one minus the coarse-grained fraction.

Aquifer test results compiled from 161 pumping tests conducted throughout the Basin were used to inform initial estimates of coarse-grained horizontal hydraulic conductivities within the model.[17] The locations of pumping test wells within the Basin are shown on **Figure 19**. A summary of horizontal hydraulic conductivities estimated from pumping tests is provided in **Table 5** below.

Initial coarse-grained hydraulic conductivities were assigned to each aquifer layer using average hydraulic conductivities calculated from pumping tests for wells whose coarse-grained fractions were in the upper 50th percentile of the texture map for that layer. The final specified coarse-grained horizontal and vertical hydraulic conductivities vary by layer and were determined by calibration, as discussed below in *Section 4.3.*

Table 5. Horizontal Hydraulic Conductivity (Kh) Estimates from Pumping Tests

Principal Aquifer Unit	Horizontal Hydraulic Conductivity (Kh), [ft/d]		
	Minimum	Average	Maximum
Dune Sand Aquifer	2.7	72	750
180/400-Foot Aquifers	0.04	168	1110
Deep Aquifer	2.2	11.6	25.4

2.5.2 Storage

As mentioned above, each Principal Aquifer unit within the Basin may experience varied degrees of confinement depending on location within the Basin, presence of overlying aquitard units, and current groundwater level conditions. As such, both the specific yield (Sy) and specific storage (Ss) parameters must be specified in order to effectively simulate transient head conditions in the Basin.

Aquifer test results compiled from 40 pumping tests conducted throughout the Basin were used to inform initial estimates of specific storage (Ss) within the model[18]. The locations of pumping test wells within the

[17] Aquifer transmissivity (T) measurements from pumping test data were converted to effective hydraulic conductivities by dividing the T value by the entire length of well screen.

[18] Confined storativity (S) measurements from pumping test data were converted to specific storage by dividing the S value by the entire length of well screen.

Basin are shown on **Figure 19**. A summary of Ss values estimated from pumping tests is provided in **Table 6** below. Final Ss values were determined by calibration, as discussed below in *Section 4.3.*

Table 6. Specific Storage (Ss) Measurements from Pumping Tests

Principal Aquifer Unit	Specific Storage (Ss) [1/ft]		
	Minimum	Average	Maximum
Dune Sand Aquifer	1.6E-05	9.5E-04	4.8E-03
180/400-Foot Aquifers	9.9E-07	3.4E-05	2.6E-04
Deep Aquifer [(1)]	N/A	N/A	N/A

Notes:

(1) No Ss data is currently available from pumping tests for the Deep Aquifer.

Very little data exists to inform estimates of specific yield within individual aquifer units of the Basin. Specific yields have been estimated to range from 0.04 to 0.4 within the Dune Sand Aquifer, and a bulk specific yield of 0.12 was used for the El Toro Primary Aquifer in prior studies (*Todd, 2016*). As such, an initial specific yield (Sy) value of 0.12 was assigned to all aquifer units in the model, consistent with values reported for silty sands in the literature. Final Sy values were determined by calibration, as discussed below in *Section 4.3.*

3. STRESSES

3.1 Recharge

Recharge is simulated using the Recharge (RCH) Package. To quantify the spatial and temporal distribution of recharge across the MBGWFM domain, a Soil Moisture Budget accounting model (SMB) was developed using *MATLAB* programming code. The SMB simulates land surface processes (e.g., precipitation, applied water, and plant evapotranspiration [ET]) and root zone processes which ultimately determine the amount of deep percolation on a grid cell basis that is specified as groundwater recharge to the uppermost active layer of the MBGWFM grid. Detailed documentation of the SMB model and associated input datasets is provided in ***Attachment 2*****.**

The SMB uses a mass-balance approach to quantify the movement of water that arrives at the land surface from either precipitation or irrigation and subsequent movement into the subsurface or atmosphere. The water movement processes included in the SMB model are (1) precipitation, (2) interception, (3) evaporation from canopy and depression storage, (4) rainfall excess runoff, (5) applied water from District deliveries, (6) applied water from private pumping (deficit pumping), (7) ET by vegetation, (8) recharge, (9) saturation excess runoff, and (10) dynamic soil moisture storage.

The SMB calculates the above processes on a grid cell basis across the entire active MBGWFM grid. Spatially variable parameters within the SMB include:

- Soil types (**Figure 20**) and properties, including soil hydrologic group (**Figure 21**), vertical hydraulic conductivity (**Figure 22**), soil depth, field capacity, wilting point, and total porosity, from the United States Department of Agriculture (USDA) Soil Survey Geographic Database (SSURGO)[19]
- Spatial land use data from the U.S. Department of Agriculture (USDA) Forest Service Region 5 Classification and Assessment with Landsat of Visible Ecological Groupings (CalVeg) dataset for Zone 5 (Central Valley)[20] and from various historical and projected land use surveys (see *Sections 3.1.1 and 3.1.2* below)
- Gridded daily precipitation data from the 4-kilometer *Parameter-elevation Regressions on Independent Slopes Model* (PRISM)[21] dataset (**Figure 23**)
- Daily reference evapotranspiration (ETo) data measured at California Irrigation Management Information System (CIMIS) Salinas North #116 and Laguna Seca #229 stations
- Water service area boundaries for the five water service areas within the Basin, including MCWD, CalAm (Ambler, Hidden Hills and Toro Units) and California Water Service (CWS) (**Figure 24**)

Additional parameters to the SMB include:

- Curve numbers for runoff for agriculture, urban, and native vegetation classifications including conifer forest/woodland, hardwood forest/woodland, mixed conifer and hardwood forest/woodland, shrub, herbaceous, and barren (*USDA, 1986*)
- Monthly crop coefficients and canopy storage properties for native, agricultural, and urban land use types from California Polytechnic State University's Irrigation Training and Research Center (*Howes et al., 2015*)

The combination of soil type and land use type determines the Curve Number (runoff coefficient) that controls rainfall excess runoff. ET is calculated for each land use type from the crop coefficient method using daily CIMIS ETo rates and monthly crop coefficients specific to the land use type. ET is limited when soil moisture declines to the wilting point. Irrigation with private groundwater occurs for irrigated agricultural lands when the combination of precipitation, applied delivered water, and soil moisture storage is insufficient to meet vegetative water demand (ET). Private groundwater pumping rates are further adjusted to account for irrigation inefficiency[22].

The SMB calculates a running soil moisture balance for each grid cell on a daily timestep and is driven by daily spatially variable daily precipitation data from the PRISM dataset. Recharge is simulated to occur when the water content in the soil column after infiltration of precipitation, applied water, and ET uptake is greater than the field capacity of the soil. When this occurs, recharge is released from the soil column to the point where soil water content equals field capacity. Daily calculated recharge rates are summed into monthly totals for use as input to the MBGWFM.

In addition to the recharge calculated by the SMB, the MBGWFM also includes water distribution and conveyance system leakage in the RCH Package. Leakage was estimated as 5% of delivered water and was uniformly distributed across all cells within each of the five water service areas in the Basin (**Figure 24**).

[20] https://www.fs.usda.gov/detail/r5/landmanagement/resourcemanagement/?cid=stelprdb5347192

[21] https://prism.oregonstate.edu/recent/

[22] A uniform irrigation efficiency of 85% was assumed in the calculation of private groundwater pumping on agricultural lands in line with values commonly employed for high-efficiency (e.g., micro-drip) irrigation systems.

A more detailed description of the transient input datasets to the SMB for the historical and projected simulations is provided below.

3.1.1 Historical Simulation

3.1.1.1 Climate

The historical SMB simulation calculates recharge rates for the period October 1, 1998 through September 30, 2018 using daily precipitation data from PRISM and daily ETo data from CIMIS as described above.

3.1.1.2 Land Use

As limited historical land use information exists within the Basin, spatial land use classifications were derived from the CalVeg dataset (10x10 meter resolution). The CalVeg land use map was further supplemented with a map of 2014 land use classes prepared by DWR to identify irrigated agricultural parcels within the Basin and their respective crop types. A single historical land use class was subsequently assigned to each active grid cell based on the dominant land use type mapped within the cell area and was assumed to remain static throughout the duration of the 20-year historical simulation. The final historical land use map is shown in **Figure 25.**

3.1.1.3 Deliveries

Monthly historical delivery records were obtained for the three water suppliers within the Basin (MCWD, CalAm, and CWS) and used to estimate historical outdoor delivery rates within each of the five water service areas in the Basin. MCWD pumping records were obtained directly from MCWD, while monthly delivery records for the each of the CalAm and CWS service areas were provided by the Seaside Basin Watermaster. As no detailed breakdown of indoor vs. outdoor deliveries was available for any of the water agency delivery records, a simplifying assumption was made that 25% of total deliveries within the service area would be used for outdoor consumption (i.e., irrigation) over a 6-month growing season (i.e., April through September). This assumption generally consistent with information provided in MCWD’s 2020 Urban Water Management Plan (UWMP, *Schaff & Wheeler, 2021*) and assumptions used in the Seaside Model (*Hydrometrics, 2019)*. Monthly outdoor deliveries were uniformly distributed across all cells within each of the five water service areas in the Basin (**Figure 24**). As mentioned above, an additional 5% of total monthly deliveries were added to the recharge outputs from the SMB for all cells within a water service area to simulate leakage contributions to the Basin. Leakage was assumed to occur throughout the entire calendar year.

3.1.2 Projected Simulations

3.1.2.1 Climate

As mentioned in *Section 2.4.2.3.2*, three climate change scenarios were modeled in the MBGWFM projected simulations. These climate change scenarios were informed by climate change modeling completed by DWR (*DWR, 2020*) and include the following:

- **Baseline Conditions –** no climate change impacts
- **2030 Climate Change (Central Tendency) –** “moderate” climate change impacts
- **2070 Climate Change (Central Tendency) –** accounts for “severe” climate change impacts

For the Baseline scenario, projected daily precipitation and ETo datasets were developed using historical PRISM and CIMIS data for the 50-year "analog" hydrologic period described in *Section 2.2.2.2*, where:

- Analog Years 1-20: Based on historical years 1999-2018
- Analog Years 21-40: Based on historical years 1999-2018
- Analog Years: 41-50: Based on historical years 1999-2008

For the 2030 and 2070 climate change scenarios, DWR provided monthly scaling factors to account for impacts of climate change on precipitation and ET rates. Precipitation and ET climate change factors are spatially variable and mapped to a variable infiltration capacity (VIC) grid (**Figure 26**). These monthly climate change factors were extracted for VIC grid cells that intersect the Basin and used to modify the 50-year historical "analog" precipitation and ET datasets developed for the Baseline projected scenario.

On average, applying the 2030 climate change factors resulted in a -0.5% decrease in precipitation rates and a +3.1% increase in ET rates throughout the Basin relative to Baseline projected conditions, while applying the 2070 climate change factors resulted in a -2.2% decrease in precipitation rates and a 7.7% increase in ET rates throughout the Basin relative to Baseline projected conditions. Notably, the DWR climate change factors dataset appears to indicate that precipitation events within the Basin are projected to be less frequent and of significantly higher intensity as climate change impacts become more severe, with a single-month maximum change in precipitation rates of +56% under the 2030 climate scenario and +71% under the 2070 climate scenario. This could result in comparatively higher average recharge rates within the Basin relative to Baseline conditions, even though total precipitation rates are projected to remain nearly constant. On the other hand, the DWR climate change dataset appears to indicate that ET rates are projected to be marginally yet consistently higher as climate change impacts become more severe, with a single-month maximum change in ET rates of +7% under the 2030 climate scenario and +17% under the 2070 climate scenario.

3.1.2.2 Land Use

For all projected scenarios, the historical land use map was updated to reflect future planned urban development and expansion of the MCWD service area in line with future land use conditions specified in MCWD's 2020 Water Master Plan (*AKEL, 2020*). Specifically, a map of future land use (Figure 2.3 of the MCWD Master Plan) was used to adjust the urban footprint within the Marina-Ord Management Area to include all future residential, commercial, industrial, institutional, and mixed-use parcels designated for development over the next 20 years (i.e., by 2040)[23]. Land use in the remaining areas of the Basin was assumed to remain constant with current conditions, in line with the assumption of no future increases in water demands within the Corral de Tierra Management Area (see *Section 3.1.2.3*). The final future land use map is shown in **Figure 27.**

Additionally, for all projected scenarios a stormwater catchment area was delineated around the future MCWD service area boundary to track urban runoff rates in the SMB. Here, an adjustment was made to the SMB code that allowed runoff on urban lands within the future MCWD service area to be re-routed into recharge as a means of directly simulating MCWD's ongoing stormwater recharge management program (see GSP *Section 9.4.4., project M1)*. The SMB estimates that full implementation of this stormwater recharge management program could provide as much as ~1,100 AFY of additional recharge to the future MCWD service area under Baseline projected conditions. It is important to note however

[23] The future (i.e., 2040) MCWD land use map was applied over the entire 50-year projected simulation period to simulate future impacts to recharge rates under full buildout of the City of Marina.

that this added recharge from stormwater capture is at least partially offset by reduced recharge in newly urbanized areas. The MCWD stormwater catchment area is included on the future land use map (**Figure 27**).

3.1.2.3 Deliveries

Projected MCWD deliveries were estimated within the SMB using projected total future water demands from 2020 through 2040 specified in Table 4.10 of the 2020 UWMP (*Schaff & Wheeler, 2021)*. Projected deliveries within the future MCWD service area are detailed in **Table 7** below.

Table 7. Projected MCWD Deliveries

Year	Projected Demand (AFY)
2020	3,367
2025	6,001
2030	7,802
2035	8,879
2040	9,584

Projected MCWD deliveries were scaled linearly over five-year increments up through 2040 (i.e., projected model year 2022), and were then held constant through the remainder of the 50-year projected simulation period.

Deliveries from all other water service areas within the Basin (including CalAm and CWS service areas) were assumed to remain constant at current (i.e., WY 2018) rates throughout the entire 50-year projected simulation period.

Consistent with the historical model, it was assumed that 25% of total projected deliveries would be applied for outdoor uses between April – September, while the remainder of deliveries would be used to meet potable and non-potable indoor demands. It was also assumed that 5% of total projected deliveries would be lost to leakage and thus contribute directly to recharge within each water service area of the Basin.

3.2 Pumping

Pumping is simulated in the MBGWFM using the Well (WEL) Package. Monthly pumping rates were estimated for all known municipal/public supply, agricultural, and domestic wells within the Basin based on available data provided by MCWD (for the Marina-Ord Management Area) and SVBGSA (for the Corral de Tierra Management Area). All pumping was vertically distributed based on available well construction information (i.e., screened interval depths or total well depths). When well construction information was unavailable, pumping was distributed based on aquifer classifications previously determined by MCWD or SVBGSA. A subset of wells are presumed to screen multiple Principal Aquifer units; for these wells, pumping was assigned proportionally to model layers based on the total screen intervals within each layer.

A summary of the datasets and assumptions used to develop historical and projected pumping datasets is provided below. Locations of the pumping wells specified in the model and their relative historical average monthly pumping rates are shown on **Figure 28**.

3.2.1 Historical Simulation

Historical pumping within the Marina-Ord Management Area was estimated from records provided by MCWD. Monthly historical pumping rates from October 1998 – September 2018 were provided for all nine (9) MCWD-owned production wells within the Basin that were in operation over the historical period.

Historical pumping within the Corral de Tierra Management Area was estimated from records provided by SVBGSA. Annual historical pumping rates from October 1998 – September 2018 were estimated for 393 known public supply, agricultural, and domestic wells based on an analysis of public water system wells and information obtained from recent water demand studies within the Corral de Tierra (*Wallace Group, 2020)*.

Additional historical pumping records were obtained from MCWRA for five MCWRA-owned wells north of the Basin boundary.

3.2.2 Projected Simulations

Projected pumping within the Marina-Ord Management area was estimated using projected MCWD water demands specified in the 2020 UWMP (*Schaff & Wheeler, 2021)* and outlined in **Table 7** above. Specifically, two projected pumping scenarios were estimated for MCWD:

- **"No-Projects" Scenario –** assumes 100% of future water demands will be met by groundwater pumping from the MCWD well network
- **"Projects" Scenario –** assumes a portion of future water demands will be met by recycled water or other augmented water supplies (see GSP *Sections 6.5.2 and 9.4.6*)

Under the "Projects" scenario, it is assumed that a portion of MCWD's projected water demand will be satisfied through some form of water supply augmentation. For evaluation purposes, the current projections assume that all recycled water generated by MCWD will be used to augment water supplies within its service area. This project is consistent with the Recycled Water Reuse Through Landscape Irrigation and Indirect Potable Reuse project described in GSP *Section 9.4.6* (project M3). Practically, projected MCWD pumping is reduced from the total projected demands specified in the 2020 UWMP to account for increased availability of recycled water (or other augmented water supplies) over the 20-year planning period. These augmented water supplies are currently modeled as "in-lieu" of groundwater pumping, i.e., through direct, proportional reductions in groundwater pumping from MCWD-owned wells relative to the "no project" scenario pumping demands.

A summary of the projected pumping rates within MCWD under each scenario is provided in **Table 8** below. For both scenarios, pumping was distributed within individual MCWD wells based on historical monthly and total pumping rates at each well[24]. All pumping was scaled linearly over five-year increments

[24] One exception to this is that all historical pumping contributions from MCWD Well 12 will be redistributed to Well 34 since Well 12 was recently taken offline.

up through 2040 (i.e., projected model year 2022), and was then held constant through the remainder of the 50-year projected simulation period.

Table 8. Projected MCWD Pumping Rates

Year	"No Projects" Scenario Pumping (AFY)	Recycled / Augmented Water Supply Offset (AFY)	"Projects" Scenario Pumping (AFY)
2020	3,367	(0)	3,367
2025	6,001	(600)	5,401
2030	7,802	(4,571)	3,231
2035	8,879	(5,129)	3,880
2040	9,584	(5,495)	4,089

Consistent with information and projections provided by SVBGSA, projected pumping within the Corral de Tierra Management Area was assumed to remain constant at current (WY 2018) rates.

4. CALIBRATION

4.1 Calibration Approach

A primary goal of model calibration is to minimize the residual (i.e., difference) between simulated and observed water levels throughout the Basin. This is primarily achieved through systematic and reasonable modifications to model parameters such that simulated water levels match well with observed measurements, both spatially and temporally. Additionally, it is important to observe and account for water budget outputs during model calibration to ensure that groundwater inflows and outflows are within reasonable ranges based on prior available information and studies conducted within the Basin.

In total, 65 unique parameters are specified within the MBGWFM. Model parameters primarily relate to aquifer properties (i.e., hydraulic conductivity and storage) defined within each model layer and for each boundary condition (e.g., conductance terms for the RIV and GHB packages). Given the high complexity and parameterization of the model, calibration was primarily conducted using a software package for Model-Independent Parameter Estimation and Uncertainty Analysis (PEST)[25]. PEST manages the systematic changes to the model parameters, runs the model multiple times, evaluates the effect on simulated water levels, and attempts to minimize model error through use of an objective function. PEST calibration is guided by user input, including specifying priors, bounds, and relationships between model parameters, and can thus be systematically applied to achieve an acceptable model error while keeping the parameter space constrained within reasonable limits.

Further details regarding the model calibration process and results are provided below.

[25] https://pesthomepage.org/

4.2 Calibration Data

Historical groundwater elevation data collected from wells located throughout the Basin were used to calibrate the model. In total, 30,354 groundwater elevation observations collected from 603 wells between October 1998 and September 2018 were used for model calibration. Calibration well locations are shown in **Figure 29**.

4.3 Aquifer Properties

As described in *Section 2.5,* preliminary estimates of aquifer properties were used as initial conditions within the MBGWFM. Through an iterative approach, the modeled water-transmitting and storage properties were calibrated by systematically adjusting the parameter values in PEST to minimize water level residuals.

The calibrated distribution of horizontal hydraulic conductivities are mapped by model layer in **Figure 30** and **Figure 31**. The calibrated distribution of vertical hydraulic conductivities are mapped by model layer in **Figure 32** and **Figure 33**. **Table 9** presents the calibrated storage parameters (including specific yield and specific storage) by model layer.

Table 9. MBGWFM Calibrated Storage Parameters

MBGWFM Layer	Specific Yield (Sy) [-]	Specific Storage (Ss) [1/ft]
1	0.12	1.0E-05
2	0.12	1.0E-05
3	0.12	5.0E-06
4	0.12	5.0E-06
5	0.12	4.0E-06
6	0.12	1.0E-05
7	0.12	3.0E-05
8	0.12	1.0E-05

4.3.1 Evaluation of Calibrated Aquifer Properties

Horizontal hydraulic conductivities (Kh) differ substantially by model layer. Within aquifer units, Kh values are generally highest in model layers 3, 5, and 7 (the Upper 180-Foot, Lower 180-Foot, and 400-Foot Aquifer) and lowest in model layer 8 (the Deep Aquifer). Kh values in aquitard units (i.e., layers 2, 4, and 6) are almost always lower than in overlying and underlying aquifer layers. Boxplots showing a comparison of Kh values estimated from pumping tests (see *Section 2.5*) and model calibrated Kh values are shown in **Figure 34**. In nearly all cases, calibrated Kh values are within the range of values estimated from aquifer pumping tests and other previous hydrogeologic studies as presented in *Section 2.5*.

Vertical hydraulic conductivities (Kv) also differ substantially by layer. Within aquifer units, Kv values are generally highest in layers 5 and 7 (Lower 180-Foot and 400-Foot Aquifers) and lowest in layer 3 (Upper 180-foot aquifer). Kv values in aquitard units (i.e., layers 2,4, and 6) are almost always lower than in overlying and underlying aquifer layers. Kv values are always lower than their Kh counterparts for each model layer, which is indicative of the vertical anisotropy in transmissivity observed within the Basin. No field estimates are currently available to validate Kv values in the Basin, though the calibrated values are generally within the range for alluvial aquifer systems and aquitard units presented in the literature (*Freeze & Cherry, 1979*).

Specific storage (Ss) values differ by aquifer layer. Within aquifer units, Ss values are highest in model layer 7 (400-Foot Aquifer) and lowest in model layers 3 and 5 (Upper and Lower 180-Foot Aquifers). In most cases, calibrated Ss values fall within the range of values estimated from aquifer pumping tests and other previous hydrogeologic studies as presented in *Section 2.5*. Calibrated Ss in model layer 1 (Dune Sand Aquifer) looks to be somewhat low compared to pumping test measurements, though layer 1 is almost always unconfined and thus Ss is usually not employed in head and storage change calculations within this aquifer unit.

Specific yield (Sy) values were ultimately held constant at 0.12 after final model calibration. This is within the range of estimates provided from prior hydrogeologic studies as presented in *Section 2.5*.

4.4 GHB Conductance

GHB conductance terms along each model boundary were ultimately coupled with the Kh values by model layer to provide for a continuous distribution in horizontal hydraulic conductivity along the Basin boundaries.

As discussed in *Section 2.4.2.2.1*, calibrated GHB conductance terms along the southern model boundary result in a reasonable match in historical estimates of Seaside Subbasin cross-boundary flows with the Seaside Model. As discussed in GSP *Section 4,* MBGWFM estimates of historical cross-boundary flows with the 180/400-Foot Aquifer Subbasin are significantly higher than analogous estimates provided in the 180/400 GSP (*SVBGSA, 2016*), though both acknowledge a consistent outflow gradient from Monterey Subbasin to the 180/400-Foot Aquifer Subbasin. This discrepancy is not surprising and well founded. Due to time constraints, historical and current water budgets presented in the 180/400 Foot Aquifer GSP were developed by aggregating data and analyses from previous reports and other available sources. No numerical modeling was completed to develop the historical or current water budget. The limitations of the historical water budget analyses included in the 180/400 Foot Aquifer GSP are well acknowledged within the GSP and additional analyses are being conducted as part of the 5-year review process.

In fact, as noted in the 180/400 Foot Aquifer GSP, the estimated inflow from the Monterey Subbasin of 3,000 AFY/year was taken from a Montgomery Watson document produced in 1997. This document generally looks at data that pre-dates the Historical Period evaluated in the Monterey GSP (1994 through 2018). It is based on a very limited data set and does not reflect conditions within these subbasins over the last 15 years. The Salinas Valley Integrated Hydrologic Model (SVIHM), which was developed by the U.S. Geological Survey (USGS) for the entire Salinas Valley Groundwater, was used to develop projected water budgets in the 180/400 Foot Aquifer GSP and water budgets for other Salinas Valley subbasins. However, as discussed in detail in Montgomery & Associates 2 April 2021 Technical Memorandum to the SVBGSA Advisory Committee (GSP Appendix 6C) "SVIHM does not accurately reflect hydrologic conditions in the Monterey Subbasin. SVIHM calibration efforts primarily focus on other portions of the Salinas Valley Groundwater Basin where there is significant agricultural groundwater use. The SVIHM was not calibrated to any groundwater level data from the Seaside Subbasin and included only one calibration location in the Monterey Subbasin. M&A believes the SVIHM is not detailed or accurate in the Monterey Subbasin." Thus, any direct comparison between cross-boundary subbasin flow estimates developed using the MBGWFM and those presented in the 180/400 Subbasin GSP or developed using SVIHM are not useful. No prior estimates of volumetric exchanges between the Monterey Subbasin and the Pacific Ocean are available for comparison.

SVBGSA is in the process of developing a variable density driven groundwater model for the coastal regions of the greater Salinas Valley Basin. This model will incorporate the MBGWFM and be used to further assess volumetric exchanges between the ocean and the Salinas Valley groundwater basin. It will also aid in evaluating flows across subbasin boundaries and will be used evaluate impacts of potential regional projects that have been proposed in this GSP and other GSPs to address seawater intrusion in the Salinas Valley groundwater basin.

4.5 Streambed Conductance

Streambed conductance terms were adjusted in PEST and range from 0.1 ft/d to 10 ft/d depending on reach and uppermost active underlying model layer. Model results indicate the Salinas River is largely hydraulically disconnected from the Basin due to its presence on top of the largely impermeable Fort Ord/Salinas Valley Aquitard. An exception to this is in the northeastern corner of the Basin within the Corral de Tierra Management Area, where the Salinas River is directly underlain by the more permeable El Toro Primary Aquifer System. Here, the Salinas River is estimated to contribute a net inflow of ~150 AFY to the Basin during the historical model period.

4.6 Recharge

Unlike with aquifer storage properties, recharge rates are difficult to quantify with precision due to the general absence of direct monitoring data to support model calibration. Recharge inputs to the MBGWFM were not explicitly included as a parameter in the PEST calibration routine, but were rather manually adjusted through systematic modifications to parameters in the SMB to ensure recharge rates were within reasonable ranges when compared to other regional models and prior studies.

Annual, historical land surface water budget outputs from the calibrated SMB model are provided for the entire Basin and by Management Area in **Appendix 6A** of the GSP (see *Tables 6A-4 through 6A-6).* On average, the calibrated SMB calculates 10,055 AFY of recharge to the Basin, or 0.33 ft/yr. This represents a normalized recharge rate of 24% of total precipitation and applied water within the Basin, which is within the range of typical recharge rates estimated for the region. Recharge rates vary significantly by year, with most recharge occurring during wet years (e.g., 0.62 ft/yr in WY 2006) and very little occurring during dry years (e.g., 0.06 ft/yr in WY 2012). Recharge rates are typically highest in undeveloped areas of the Basin and are lowest in urbanized areas with significant impervious lands.

As part of SMB calibration, recharge outputs were compared to analogous outputs from the Salinas Valley Integrated Hydrologic Model (SVIHM)[26] (**Figure 35**). The SVIHM employs the MODFLOW Farm Package to estimate recharge rates, which functions similarly to the SMB developed for the MBGWFM. Comparison between the SMB and SVIHM indicates that average Basin-wide recharge rates calculated from the SMB are +12% higher than those calculated from the SVIHM over like timeframes. However, it is important to note that data and assumptions on land use classes, applied water, and other parameters differ between

[26] *Ibid [14].*

the two models, and thus a direct comparison of recharge volumes may be misleading. When looking closer at normalized recharge rates, it appears that the SMB and SVIHM track very closely in most areas of the Basin. For example, the SMB calculated ~25.3% of total precipitation and applied water as contributing to recharge in the Corral de Tierra Management Area, compared to ~25.6% calculated from the SVIHM. The most significant difference between the two models is within urban areas, where the SMB calculates ~11.6% recharge of precipitation and applied water compared to ~5.8% calculated from SVIHM. Notably, the SVIHM does not appear to account for deliveries from the various water suppliers within the basin in its Urban "farm", which may in part explain the discrepancy. The SVIHM also does not account for leakage from water conveyance systems within these areas. Therefore, it appears the discrepancy in Basin-level recharge between the two models can be primarily explained by differences in input datasets and assumptions between the two models rather than fundamental differences in recharge calculation methodologies.

4.7 Calibration Results

MBGWFM calibration was assessed using statistics calculated from the differences between observed and simulated water levels (residuals), a map of residuals, plots of calibration results, and hydrographs of observed and calculated water levels. Final model calibration statistics are summarized by aquifer layer and for the entire model in **Table 10**.

Table 10. MBGWFM Calibration Statistics

MBGWFM Layer	Water Level Count	Range in Observations (ft)	Mean Residual (ft)	Residual Standard Deviation (ft)	RMSE (ft)	Normalized RMSE (%)
1	11,941	123.2	-0.3	11.3	11.3	9.2%
3	9,032	98.7	-2.1	5.2	5.7	5.7%
5	4,785	74.6	-6.5	3.5	7.3	9.8%
7	1,836	119.9	-5.0	5.2	7.2	6.0%
8	3,210	728.4	7.1	19.6	20.8	2.9%
ALL	**30,354**	**728.4**	**-1.3**	**10.7**	**10.8**	**1.5%**

The root-mean square error (RMSE)[27] for the entire model is **10.8 ft** and the mean residual (error) is **-1.3 ft**, indicating that simulated water levels are underestimated by 1.3 ft on average. The normalized RMSE, expressed as a percent of the observed range in water levels, is below 10% within individual model layers and **1.5%** for the entire model. A generalized rule of thumb in model calibration is that the model is considered well-calibrated when the normalized RMSE is less than 10%.[28] The low normalized RMSEs are therefore an indicator that the model is well-calibrated as a whole and within individual layers given the range of observed data.

[27] RMSE is a quantitative measure of the closeness of fit and is calculated as the square root of the average squared residuals.

[28] If there is a large range in observed water levels, as is the case in the MBGWFM, normalized calibration metrics can be less reliable (Anderson and Woessner, 1991).

A scatter plot of calculated vs. observed water levels and a histogram of residuals are shown in **Figure 36**. In a perfect calibration, the points would plot exactly along the solid 1:1 match line. Points above the line represent simulated water levels that are overestimated relative to observed data and points below the line represent simulated water levels that are underestimated relative to observed data. The scatter plot shows a fairly equal distribution of points above and below the line. The slope of the regression line (0.97) and near-zero intercept (-0.68) indicates that there is a good match between calculated and observed water levels, with only a slight negative bias in the residuals. The histogram of residuals shown on **Figure 36** are roughly evenly distributed around a mean of -1.3 feet with a standard deviation of 10.7 feet. Most residuals lie within one standard deviation of the mean. The slight bias of residuals to the negative side of zero indicates that the simulated water levels tend to be slightly smaller than observed water levels.

Average residuals are shown by well on **Figure 37**. Residuals are representative of site-specific errors between the modeled and observed water. A positive value indicates simulated water levels are greater than observed water levels and a negative value indicates simulated water levels are less than observed water levels. Average residuals are spatially variable, though some patterns appear to exist within individual model layers:

- In Layer 1, simulated water levels are generally overestimated at wells located near the coast and underestimated at wells located east of the City of Marina;
- In Layer 3, simulated water levels are underestimated by ~13 feet on average at the cluster of wells located just south of the Salinas River, and by ~3 feet on average at the cluster of wells located along the coast;
- In Layer 5, simulated water levels are persistently underestimated by ~6 feet on average at all observation wells;
- In general, the greatest residuals occur within the Corral de Tierra Management Area in model Layer 8, where limited historical water level data are available to inform model calibration. Simulated water levels are overestimated by ~18 feet on average within the Corral de Tierra Management Area, though residuals range from +79 feet to -46 feet at individual wells.

The high residuals observed at calibration wells in the Corral de Tierra Management Area can in part be explained by the simplified conceptualization and model representation of the aquifer system in this portion of the Basin. As described in *Section 2.2.3*, a single principal aquifer unit (the “El Toro Primary Aquifer”) has been defined within the Corral de Tierra and is currently being represented in the MBGWFM using a single model layer (Layer 8). As further described in *Section 4* of the GSP, historical water level measurements collected from wells screening the El Toro Primary Aquifer can vary substantially with well depth, indicating the presence of vertical gradients. These depth-dependent trends in measured water levels within the El Toro Primary Aquifer Unit contribute to the high range and magnitude in residuals seen at Layer 8 wells within the Corral de Tierra portion of the MBGWFM. In general, the historical model tends to overestimate simulated water levels at calibration wells screening the shallow portion of the El Toro Primary Aquifer Unit (e.g., MPWMD FO-05S) and underestimate water levels at the deeper screened calibration wells (e.g., MPWMD FO-05D).

Hydrographs of simulated and observed water levels are included in ***Attachment 1*.** The locations of wells with hydrographs are shown on **Figure 29**. Hydrographs of measured and simulated water levels generally match well for most wells within the Basin, especially within model layers 1, 3, 5, and 7. As mentioned above, model errors are noticeably greater at certain wells in model layer 8, where less data is available to inform aquifer properties and their spatial and vertical distribution. A more complete discussion of model limitations and suggested future refinements is provided in *Section 6* below.

5. SENSITIVITY ANALYSIS

A sensitivity analysis was conducted to evaluate the effects of changing model parameters on model calibration. The analysis was conducted by changing model parameters in a systematic way and assessing the impact on the simulated water levels. The sensitivity analysis was conducted using PEST. PEST manages the systematic changes to the model parameters, runs the model multiple times, evaluates the effect on simulated water levels, and calculates the composite sensitivities for each parameter of interest.

The composite sensitivity was calculated for **65** parameters representing horizontal hydraulic conductivity, vertical hydraulic conductivity, specific storage, specific yield, general-head boundary conductance, and streambed conductance. The composite sensitivities were calculated for each layer represented by these parameters. Composite sensitivities for the 10 most sensitive parameters are shown in **Figure 38.** These 10 parameters represent 99.8% of the total composite sensitivities in the model. The composite sensitivities for the 54 parameters not shown in the figure are each less than 0.13%.

The most sensitive parameters in the MBGWFM are, by relative order: (1) the vertical hydraulic conductivity of Layer 2 (the Fort Ord/Salinas Valley Aquitard); (2) the specific storage values for all layers; and (3) the specific yield values for layer 1.

Vertical conductivity (Kv) in layer 2 appears to govern how much recharge enters the lower layers of the model versus being withheld within layer 1 (i.e., the Dune Sand Aquifer). As such, it is to be expected that Kv of layer 2 will have a substantial influence on simulated water levels in all layers. The final calibrated Kv of layer 2 was set at 2.0E-4 ft/d, in line with typical vertical conductivities for a clay-rich confining unit (*Freeze & Cherry, 1979)*. Additional data collection regarding seepage rates through the Salinas Valley Aquitard and interconnectivity between the Dune Sand and underlying 180-Foot Aquifer could help further constrain this parameter and thus improve model calibration.

There are very little data characterizing specific storage or specific yield values in the Basin apart from a limited number of pumping test measurements (see *Section 2.5.2*), which are in themselves quite variable. Given the uncertainty in measured values of specific storage and specific yield and the high sensitivity of these parameters, additional data collection (e.g., more pumping tests) could help constrain the range of values specified in the model.

Sensitivity analysis was performed on inputs to the SMB to determine which inputs have the largest impacts on recharge outputs. Recharge calculations in the SMB were found to be most sensitive to precipitation and ET inputs. Precipitation input to the SMB was estimated using PRISM data and ET input was estimated using crop coefficients and CIMIS reference evapotranspiration data (see *Section 3.1)*. A 10% change in precipitation input to the SMB model resulted in a 7% change in recharge. A 10% change in ET input to the SMB resulted in a 7% change in recharge. Recharge is less sensitive to other parameters and assumptions in the SMB such as soil depth, depression storage, and the ET stress function multiplier.

6. MODEL LIMITATIONS AND SUGGESTED FUTURE REFINEMENTS

Numerical models are mathematical representations of physical systems. They have limitations in their ability to represent physical systems exactly and due to limitations in the data inputs used. There is also inherent uncertainty in groundwater flow modeling itself, since mathematical (or numerical) models can only approximate physical systems and have limitations in how they compute results. However, DWR recognizes that although models are not exact representations of physical systems because mathematical depictions are imperfect, they are powerful tools that can provide useful insights (*DWR, 2018*).

The MBGWFM was developed using established scientific practices and principals for groundwater flow simulation and calibrated using the best available data within the Basin. Inputs to the models are carefully selected using best available data, the model's calculations represent established science for groundwater flow, and the model calibration error is within acceptable bounds. Therefore, the models are the best available tools for estimating water budgets and simulating projected groundwater conditions. As demonstrated by the calibration error statistics summarized in *Section 4.7* the MBGWFM reasonably represents historical groundwater conditions within the Subbasin using a set of parameters that are within the range of real-world observations and established scientific principles.

As is the case with any numerical groundwater flow model, the MBGWFM is subject to uncertainties and data gaps in hydrogeologic conceptualization (e.g., depth and extent of principal aquifer units), model parameterization (e.g., aquifer transmitting and storage properties) and calibration data (i.e., historical water level monitoring data), and simulated stresses (e.g., recharge, pumping, and boundary conditions). Here, "uncertainty" refers to the incomplete understanding of the physical setting, characteristics, and current conditions that significantly affect calculation of the water budgets presented above. "Data gaps" refer to limitations in the spatial coverage of measured data, or periods of time when no data are available. Each of these main categories of uncertainty and/or data gaps contribute to overall uncertainty in the water budget outputs from MBGWFM.

A summary of the main limitations of the model and corresponding water budgets identified from this analysis is provided below.

- **Uncertainty in Simulated Boundary Conditions.** As described in *Section 2.4.2*, inter-basin cross-boundary flows were simulated at the 180/400 Foot Aquifer Subbasin boundary based on historical groundwater elevation measurements from nearby wells, at the Seaside Subbasin boundary based on outputs from the historical Seaside Basin Groundwater Flow Model (*Hydrometrics 2009 & 2018*), and at the Monterey Coast based on freshwater equivalent sea levels. The datasets and assumptions used to model boundary conditions at each Subbasin boundary are subject to their own uncertainties, data gaps, and limitations, including:
    - *Lack of Deep Aquifer wells with historical data in the 180/400 Foot Aquifer Subbasin.* As described in *Section 2.4.2.1*, only a small number of wells exist in the Deep Aquifer within the 180/400 Foot Aquifer Subbasin with observed water level data spanning the full duration of the Historical Period. As such, simulated Deep Aquifer heads along the northern model boundary are subject to the limitations in available data to the north of the boundary, which may impact resulting calculations of 180/400 Foot Aquifer Subbasin exchanges within the water budget.
    - *Incomplete conceptualization of Principal Aquifer units in the Seaside Basin Groundwater Flow Model.* As described in *Section 2.4.2.2*, The Seaside model does not explicitly simulate groundwater flow from each Principal Aquifer unit defined in the Monterey Subbasin GSP, but rather uses a unique conceptualization of aquifer units that is primarily based on the main geologic formations encountered in the Seaside Area Subbasin (i.e., the Aromas Sands, Paso Robles Formation, and Santa Margarita/Purisima Formations). As such, there is considerable uncertainty surrounding the assumptions employed to link outputs from the Seaside model to individual layers of the MBGWFM, which may impact resulting calculations of Seaside Area Subbasin exchanges within the water budget.

- *Uncertainty in freshwater equivalent head calculations at the Monterey Coast.* As discussed in *Section 2.4.2.3*, freshwater equivalent sea levels at the Monterey Coastline are calculated based on the USGS equivalent freshwater head formula (*Guo & Langevin, 2002)*. The depths and distances at which principal aquifer units outcrop along the seafloor were estimated to inform corresponding freshwater equivalent heads at the aquifer-seafloor interface. There is considerable uncertainty surrounding the depths and distances at which each principal aquifer unit comes in contact with the sea floor, which may impact resulting calculations of Ocean exchanges within the water budget.

- **Uncertainty in Pumping Estimates within the Corral de Tierra (CDT) Management Area.** Very limited historical groundwater pumping data are available for the CDT Management Area. As such, CDT groundwater pumping demands were estimated for small water systems and domestic wells by SVBGSA using extraction reported to MCWRA and SWRCB where available, and approximated based on the number of deliveries for the small water systems and parcel size for the *de minimis* users (i.e., domestic wells). Therefore, the accuracy of CDT groundwater pumping estimates included in the water budget is limited by the lack of available pumping data and uncertainty in the CDT pumping estimates provided by SVBGSA.

- **Uncertainty in Deep Aquifer Representation.** Groundwater elevation data collected from the Deep Aquifer and the El Toro Primary Aquifer System (both represented by model layer 8) show heterogeneous conditions in the upper and lower portions of these aquifers. As discussed in GSP *Section 5*, a vertical gradient exists between the Paso Robles and Santa Margarita formations of the El Toro Primary Aquifer System. In addition, heterogeneous groundwater elevations were observed in the shallow and deep screens of Deep Aquifer well clusters as shown in GSP Figure 5-14. However, currently there is not enough spatial coverage of data to characterize the upper and lower portions of these aquifers as separate aquifers. Refining representation of the Deep Aquifer(s) and the El Toro Primary Aquifer System will facilitate connectivity between the MBGWFM and the Seaside Subbasin Model, and therefore refine calculation of inter-basin flows. Additional data is needed within both (a) the Monterey Subbasin to characterize and calibrate upper and lower portions of these aquifers and (b) the adjacent subbasins to establish boundary conditions.

- **Lack of Water Level Calibration Data.** Though the MCWD service area, former Fort Ord Site, and CWS/Cal-Am water service areas within CDT are well monitored, very limited historical groundwater elevation data exists in other portions of the Basin including near the Reservation Road area, in the Fort Ord Hills, and within the Deep Aquifer unit. As such, MBGWFM calibration in these areas is limited by the lack of available calibration data to quantify model error and inform localized adjustments to model parameterization.

- **Climate Change Uncertainty.** As described in *Section 3.1.2.1*, climate change scenarios were developed based on DWR's 2030 and 2070 Central Tendency climate modeling scenarios (DWR, 2020). These climate scenarios provide a standard framework for defining what might be considered the most likely future climate conditions within the Basin; however, they are inherently subject to considerable uncertainty. As stated in DWR (2018):

  - *"Although it is not possible to predict future hydrology and water use with certainty, the models, data, and tools provided [by DWR] are considered current best available* science *and, when used appropriately should provide GSAs with a reasonable* point *of reference for future planning."*

  - *"All models have limitations in their interpretation of the physical system and the types of data inputs used and outputs generated, as well as the interpretation of outputs. The climate models used to generate the climate and hydrologic data for use in water budget development were recommended by [the DWR Climate Change Technical Advisory Group] for their applicability to California water resources planning."*

- **Uncertainty in Aquifer Parameters.** As described in *Section 5*, a sensitivity analysis was performed to identify the most sensitive aquifer parameters that will impact simulated water levels and was subsequently used to direct further calibration efforts. In general, it was discovered that the model was most sensitive to specific storage parameters in each principal aquifer unit as well as the vertical hydraulic conductivity in the Fort Ord/Salinas Valley Aquitard. These aquifer parameters were further calibrated using a combination of PEST calibration procedures and professional judgement. As described in *Section 4*, all final calibrated aquifer parameters fall within their respective ranges reported in available pumping test data collected from wells within the Basin.

Abbreviations
DWR = California Department of Water Resources
ft = feet
MBGWFM = Monterey Subbasin Groundwater Flow Model

Notes
1. All locations are approximate.
2. Average residuals are calculated as the difference between model-calculated and observed water levels. A larger residual magnitude equates to a larger model error at the well.

Sources
1. DWR groundwater basins are based on the boundaries defined in California's Groundwater, Bulletin 118 - 2018 Update.
2. Basemap courtesy of ESRI.

Attachment 2. Soil Moisture Budget Accounting Model Documentation

SOIL MOISTURE BUDGET ACCOUNTING MODEL DOCUMENTATION

TABLE OF CONTENTS

1. INTRODUCTION

A Soil Moisture Budget (SMB) accounting model (SMB model) was developed to provide groundwater recharge estimates for use as input to the Monterey Subbasin Groundwater Flow Model (MBGWFM). This documentation presents a description of the hydrologic processes included in the SMB model along with the associated calculations/equations, the data requirements, the model calculations/equations, and the model execution process.

1.1 Purpose and Objectives of the Soil Moisture Budget Accounting Model

As described in detail in *Appendix 6-B* of the 2022 Monterey Subbasin Groundwater Sustainability Plan (GSP or Plan), the MBGWFM is a numerical model that calculates the movement of groundwater and surface water into, within, and out of the Monterey Subbasin (Basin) by discretizing the three-dimensional model domain horizontally into a grid of cells and vertically into eight layers. Like all groundwater models, the MBGWFM relies on various user-specified inputs related to aquifer hydraulic properties, initial conditions, and boundary conditions to represent the Basin and its transient hydrologic functioning. One of the main boundary condition inputs required for the MBGWFM is the aerial recharge rate to the Basin as a function of space (location) and time. The purpose of the SMB model described herein is to estimate spatiotemporal recharge rates and generate the associated input datasets for use in the MBGWFM.

1.2 SMB Model Background

1.2.1 Conceptual Approach

The SMB model uses mass-balance principles to quantify and track the movement of water that arrives at the land surface from either precipitation or irrigation into the subsurface or back into the atmosphere, based on the processes and spatially- and temporally variable factors that control recharge and groundwater pumping. The order of calculations is generally consistent with the sequence of hydrologic processes that govern this movement of water, as discussed further in *Section 2* below. At each stage in the calculation for a given time step, the volume of water in the system (consisting of soil moisture in the soil/root zone and canopy/depression storage) is balanced in accordance with the various inflows or outflows associated with the hydrologic process at that stage.

1.2.2 Spatial Approach

The SMB model performs calculations on a grid cell basis using the same spatial grid as the MBGWFM. Within each time step, calculations are performed for all active model grid cells simultaneously using vector operations. As discussed in greater detail in *Section 3* below, spatial properties assigned to grid cells vary depending on location (e.g., within a water service area), land use, and soil type characteristics. The model therefore provides spatially-variable recharge estimates that reflect variable land use, soil conditions, and imported water availability throughout the Basin. The SMB model also calculates spatially-variable private agricultural groundwater pumping demands based on evapotranspiration (ET), surface water deliveries, and irrigation efficiency, for use in calculating residual irrigation requirements and associated total applied water and recharge rates on agricultural lands.

1.2.3 Temporal Approach

The SMB model runs using a daily time step. As discussed in greater detail in *Section 3* below, the various transient input datasets vary in their temporal resolution (e.g., precipitation and potential evapotranspiration data is daily, whereas water deliveries data is monthly, and land use is held constant). The outputs from the model are monthly to be consistent with the stress periods of the MBGWFM. The decision to use a daily time step in the SMB model is driven largely by the need to incorporate the rainfall-runoff process which functions at a relatively high temporal frequency; use of a longer time step would obscure the high frequency behavior of the system.

1.2.4 Code Setup and Execution

The SMB model is written and run in the Octave programming language. During model execution, the model first reads in a set of user-prepared input datasets (discussed further in *Section 3* below) and sets up various variables and parameters. The model then runs through soil moisture budget accounting calculations for each time step in the specified simulation period. The calculations associated with each relevant hydrologic (or water movement) process are presented in *Section 2* below. In addition to the hydrologic processes described below, a set of "bookkeeping" calculations are performed at the start of each time step related to updating the various grid cell properties as needed. After the last time step is completed, the model performs final calculations to sum daily values into monthly values and writes the output data to files.

2. PROCESSES INCLUDED IN THE SMB MODEL

The water movement processes included in the SMB model are (1) precipitation, (2) interception, (3) evaporation from canopy and depression storage,(4) rainfall excess runoff, (5) applied water from District deliveries, (6) applied water from private pumping (deficit pumping), (7) ET by vegetation, (8) recharge, (9) saturation excess runoff, and (10) dynamic soil moisture storage. Each of these processes is described below along with the associated calculations/equations.

2.1 Precipitation

Precipitation is an input to the SMB model rather than a calculated variable. The precipitation data used in the SMB model is gridded daily precipitation from the Parameter-elevation Regressions on Independent Slopes Model (PRISM) dataset developed by the Northwest Alliance for Computational Science and Engineering (NACSE) based at Oregon State University. The spatial resolution of the gridded precipitation data is 4 kilometers (km).

2.2 Interception

Interception occurs when rainfall is caught by the vegetation canopy (leaves, stems, etc.) before reaching the ground. Intercepted rainfall accumulates within the canopy storage and is then subject to evaporation. The similar process of depression storage, where water accumulates in depressions on the soil surface, is treated the same way as interception in the SMB model. The model uses a running canopy storage budget for each grid cell to track the accumulation and evaporation of intercepted rainfall and depression storage, collectively referred to as interception.

$$interception = \max\left(0\middle|\min(rainfall|stor\ cap_{canopy} + stor\ cap_{depr} - CS_0)\right) \quad (1)$$

where *stor cap*$_{canopy}$ and *stor cap*$_{depr}$ are the canopy storage capacity and depression storage capacity, respectively.

$$CS_1 = CS_0 + interception \quad (2)$$

where CS is the volume (depth) of canopy and depression storage and the subscripts indicate an order of calculation.

2.3 Evaporation from Canopy and Depression Storage

Evaporation from canopy and depression storage is the removal of water from the vegetation canopy and soil surface through the meteorological process of evaporation. The evaporated water is lost to the atmosphere. This evaporation does not go towards satisfying the vegetation's transpiration demand but does use a portion of the potential evapotranspiration available from meteorological conditions (i.e., temperature, humidity, windspeed, etc.).

$$AET_c = \min(PET|CS_1) \quad (3)$$

where AET_c is the actual evaporation from canopy and depression storage and PET is the potential evapotranspiration. For the MBGWFM SMB, all land use classes rely on California Irrigation Management Information System (CIMIS) reference evapotranspiration (ETo) data and the crop coefficient method to calculate PET, as further described in *Section 2.8* below.

$$CS_2 = CS_1 - AET_c \quad (4)$$

$$PET_{leftover} = PET - AET_c \quad (5)$$

$$rainfall_{leftover} = rainfall - interception \quad (6)$$

The subscript "leftover" indicates that portion of either rainfall or PET that is not yet used at this point in the SMB model calculation.

2.4 Rainfall-Excess Runoff

Precipitation in excess of interception reaches the land surface and under certain conditions can become runoff (i.e., overland surface flow). Rainfall-excess runoff occurs when the rate of precipitation exceeds the rate at which water can move downwards through the soil. In the SMB model, rainfall-excess runoff is estimated using the U.S. Department of Agriculture (USDA) Natural Resource Conservation Service (NRCS) Curve Number approach. Under this approach, runoff is a function of rainfall amount and surface properties including the land cover type and soil hydrologic group.

$$S = \frac{1000}{CN} \quad (7)$$

$$S_{adj} = S * \left(1 - \max\left(0\middle|\frac{SM_1 - \left(\frac{FC+WP}{2}\right)}{SM_{sat} - \left(\frac{FC+WP}{2}\right)}\right)\right) \quad (8)$$

where S is the maximum retention, CN is the curve number (a function of land cover type and soil hydrologic group), FC is the field capacity and WP is the wilting point (both functions of soil type), SM is the soil moisture (inches) at that grid cell (a transient variable calculated by the model), and SM_{sat} is the soil moisture at saturation. Equation (8) essentially adjusts the S parameter for varying antecedent moisture conditions, and thus the "adj" subscript is applied.

$$Ia_{adj} = 0.2 * CN_{adj} \tag{9}$$

where Ia is the initial abstraction (initial loss).

For cells where $rainfall_{leftover} - Ia_{adj} > 0$ and $rainfall_{leftover} - Ia_{adj} - CN_{adj} > 0$

$$Runoff_{CN} = \frac{(rainfall_{leftover} - Ia_{adj})^2}{rainfall_{leftover} - Ia_{adj} - CN_{adj}} \tag{10}$$

$$rainfall_{leftover} = rainfall_{leftover} - Runoff_{CN} \tag{11}$$

where $Runoff_{CN}$ is the volume (depth) of rainfall-excess runoff via the Curve Number approach.

2.5 Applied Water from District Deliveries

District delivery records are used to estimate applied surface water[1] rates to lands within their respective water service areas within the Basin. Deliveries data were provided on a monthly basis and are therefore first normalized to a daily basis by dividing by the number of days in the month.

Within the Monterey Subbasin, all district deliveries are designated for urban use (i.e., there are no deliveries to agricultural customers). Historical distributions of indoor vs. outdoor urban water use were not available at a monthly resolution, and thus a few simplifying assumptions had to be made to parse District delivery records into their indoor and outdoor water use fractions using information obtained from the individual water agencies' Urban Water Management Plans (UWMPs). Ultimately, the applied surface water term ($SW_{applied}$) was calculated by multiplying total deliveries from each district by a user-specified fraction of outdoor water use:

$$SW_{applied} = Total\ Deliveries * Outdoor\ Water\ Use\ Fraction \tag{12}$$

The outdoor water use fraction was set at 25% for all water service areas within the Basin and was held constant throughout the simulation. Given that outdoor urban water use is generally limited to the summer months, applied surface water on urban lands was further constrained to only occur from April through September.

Monthly applied surface water volumes were distributed equally among all cells within each respective water service area.

[1] Not all District-delivered water is surface water; however, for purposes of this documentation, the term $SW_{applied}$ refers to all District-delivered water regardless of the actual source of the water.

2.6 Interim Calculations of Soil Moisture, Soil Water Content, Available Water, ET Stress Function, and Vegetative Water Demand

While not strictly a water movement or hydrologic process, the SMB model performs a set of interim calculations prior to the calculation of applied water from District deliveries. These interim calculations include updating soil moisture (SM), soil water content (SWC, expressed as a percentage of total soil volume), available water (AW), as follows:

$$SM_2 = SM_1 + rainfall_{leftover} + SW_{applied} \tag{13}$$

$$SWC_2 = \frac{SM_2}{rootdepth} \tag{14}$$

$$AW_2 = SWC_2 - WP \tag{15}$$

Calculation of an ET Stress Function ($ETSF$) allows for a reduction in vegetative water demand under dry soil conditions for the grid cells that are not irrigated up to full PET (i.e., the native and urban land cells).

$$ETSF = \max\left(0\middle|\min\left(1\middle|\frac{AW_2}{(FC-WP)*ETSF_{mult}}\right)\right) \tag{16}$$

where $ETSF_{mult}$ is the user-specified ETSF multiplier ($ETSF_{mult} = 0.5$ for the Monterey SMB).

As mentioned previously, the Vegetative Water Demand (VWD) is calculated using the crop coefficient method for all land use classes within the Basin. For agricultural land cells, VWD is calculated by multiplying the leftover PET by land use-specific crop coefficients:

$$VWD = PET_{leftover} * crop\ coeff \tag{17}$$

For urban and native land cells, VWD is further constrained by the ET Stress Function, as follows:

$$VWD = PET_{leftover} * crop\ coeff * ETSF \tag{18}$$

2.7 Applied Water from Private Groundwater Pumping

Private groundwater pumping on agricultural lands is estimated in the SMB model as the amount of residual water required to meet the vegetative water demand after accounting for leftover precipitation ($rainfall_{leftover}$) and applied surface water ($SW_{applied}$), adjusted for irrigation efficiency (IE):

$$pumping_{initial} = \max\left(0\middle|\left(\frac{VWD - rainfall_{leftover}}{IE}\right) - SW_{applied}\right) \tag{19}$$

Pumping can be limited by a user-defined pumping limit applied on a cell basis (allowing for pumping to be turned off, if needed for certain cases), as follows:

$$pumping = \min(pumping_{initial} | pumping\ limit) \tag{20}$$

The difference between the initial pumping estimate and the potentially limited pumping is tracked as a pumping deficit for later use in the actual soil/root zone ET calculation:

$$pumping_{deficit} = pumping_{init} - pumping \tag{21}$$

2.8 Evapotranspiration by Vegetation

As described above, the SMB model uses CIMIS ET and crop coefficients as the basis for PET for all lands within the Monterey Subbasin. CIMIS is a program unit in the Water Use and Efficiency Branch, California Department of Water Resources that manages a network of over 145 automated weather stations in California, which provides reference evapotranspiration (ETo) values based on surface weather stations.

Actual ET from the root/soil zone is calculated differently for agricultural land cells than for urban and native land cells. For agricultural lands (including golf courses), the actual ET is equal to the full VWD and is satisfied by a combination of applied surface water and/or private pumping, minus pumping deficit due to pumping limits:

$$AET_s = \max(0|VWD) \tag{22}$$

For urban and native lands, the actual ET is the lesser of the VWD and the available moisture above the wilting point:

$$AET_s = \min\left(VWD\middle|SM_2 - (WP * root\ depth)\right) \tag{23}$$

For all grid cells, the soil moisture is updated at this point as follows:

$$SM_3 = SM_2 + pumping - AET_s \tag{24}$$

2.9 Aerial Recharge

Aerial recharge is the process of water movement below the bottom of the root zone where it then travels by gravity through the unsaturated zone to the saturated zone, adding to groundwater storage. Additional types of recharge such as stream recharge also occur and are accounted for in the MBGWFM separately from the aerial recharge calculated with the SMB model. Aerial recharge occurs when the soil moisture exceeds the field capacity of the soil, and continues until the soil moisture reaches field capacity. It is also subject to a maximum daily recharge limit.

$$recharge = \max\left(0\middle|\min\left(max\ daily\ recharge\middle|SM_3 - (FC * root\ depth)\right)\right) \tag{25}$$

Soil moisture is once again updated after recharge:

$$SM_4 = SM_3 - recharge \tag{26}$$

2.10 Saturation Excess Runoff

Saturation excess runoff occurs when the soil becomes completely saturated due to high rates of rainfall or applied water exceeding the rate at which recharge can drain water from the soil. This process is relatively common in areas with shallow water tables but is relatively rare in the Basin due to the thick unsaturated zones and relatively permeable soils.

$$Runoff_{SE} = max\left(0 \middle| SM_4 - (porosity * root\ depth)\right) \quad (27)$$

Soil moisture and soil water content are updated one final time:

If $Runoff_{SE} > 0$

$$SM_5 = porosity * root\ depth \quad (28)$$

If $Runoff_{SE} = 0$

$$SM_5 = SM_4 \quad (29)$$

$$SWC_5 = \frac{SM_5}{root\ depth} \quad (30)$$

2.11 Soil Moisture Storage

Soil moisture storage provides a short-term reservoir allowing for the relatively continuous outputs to evapotranspiration and transpiration from the discontinuous rainfall and applied water inputs. Soil moisture storage typically varies between field capacity, which is the maximum quantity of water that can be held in the soil against gravity, and wilting point that is the threshold under which vegetation cannot extract water further. During wet periods soil moisture may rise temporarily above field capacity. Soil moisture storage is a key component of the SMB model and is updated at several points during the calculation of each time step, per equations (13), (24), (26), and (29).

3. INPUT DATASETS

This section describes the input datasets used to develop and apply the SMB model for the MBGWFM. These datasets provide the spatial and temporal information on factors that control the movement of water through the SMB model.

3.1 Grid Data

The following attributes are assigned by the SMB model to grid cells, based on input datasets that were developed using a combination of Geographic Information System (GIS) and spreadsheet analysis.

- Active cell: flag specifying whether the grid cell is active (i.e., in the MBGWFM) or inactive
- Grid area: specifies the area of the grid cell (in square feet)
- Soil code: code corresponding to the soil map unit key; soils data were obtained from the United States Department of Agriculture (USDA) Soil Survey Geographic Database (SSURGO)[2]
- District: location within a water service area (if any), based on the boundaries for the five water service areas within the Basin, including MCWD, CalAm (Ambler, Hidden Hills and Toro Units) and California Water Service (CWS)

[2] https://www.nrcs.usda.gov/wps/portal/nrcs/detail/soils/survey/?cid=nrcs142p2_053627

- Land use (static): based on land use information obtained from the U.S. Department of Agriculture (USDA) Forest Service Region 5 Classification and Assessment with Landsat of Visible Ecological Groupings (CalVeg) dataset for Zone 5 (Central Valley)[3] and from various historical and projected land use surveys conducted by MCWD
- PRISM cell identifier: 4-kilometer PRISM cell identifier for use in linking SMB grid cells to PRISM[4] precipitation data (below)

3.2 Climate Data

The following datasets are used to define the climate characteristics for the SMB model period.

- CIMIS ETo: Daily ETo data from the CIMIS Salinas North #116 and Laguna Seca #229 stations
- PRISM precipitation: gridded daily precipitation data from the PRISM dataset.

3.3 Deliveries Data

Monthly surface water delivery data from the five water agencies within the Basin (MCWD, CWS, Cal Am Ambler, Hidden Hills, and Toro Units) is used to inform applied surface water volumes in each respective water service area

3.4 Other Data

Several other datasets are used as input including the following:

- Soil characteristics: based on SSURGO soils data (see above)
- Curve Number: by land use class and hydrologic soil group, from the USDA (*USDA, 1986*)
- Canopy Storage: from California Polytechnic State University's Irrigation Training and Research Center (*Howes et al., 2015*)
- Stress periods: corresponding to the month and year of the historical simulation

3.5 User-Specified Parameters

In addition to the spatial and temporal datasets described above, the SMB model uses several parameters to modify certain inputs or calculations for purposes of model calibration.

- Depression storage capacity: set at 0.33 inches;
- ETSF multiplier: set at 0.5;
- Irrigation efficiency: set at 85%
- Outdoor water use fraction: set at 25%; only applied from April - September

SUBJECT: Monterey Subbasin Modeling

INTRODUCTION

Two groundwater models have been developed that encompass the Monterey Subbasin, and which could potentially be used to prepare the Monterey Subbasin Groundwater Sustainability Plan (GSP). These models include:

- The **Salinas Valley Integrated Hydrologic Model (SVIHM)** developed by the U.S. Geological Survey (USGS)), including its future version, the Salinas Valley Operational Model, or SVOM, which encompass the entire Salinas Valley Groundwater Basin; and
- The **Monterey Subbasin Model** developed by Marina Coast Water District Groundwater Sustainability Agency's (MCWD GSA) consultant EKI Environment & Water, Inc. (EKI), which encompasses the Monterey Subbasin and incorporates observed boundary conditions with the adjoining Seaside Subbasin and the 180/400 Foot Aquifer Subbasin.

SVBGSA recently obtained the SVIHM, and Montgomery & Associates (M&A) has been reviewing the SVIHM and developing water budgets based on model results. M&A's review suggests that the SVIHM does not accurately reflect hydrologic conditions in the Monterey Subbasin. SVIHM calibration efforts primarily focus on other portions of the Salinas Valley Groundwater Basin where there is significant agricultural groundwater use. The SVIHM was not calibrated to any groundwater level data from the Seaside Subbasin and included only one calibration location in the Monterey Subbasin. M&A believes the SVIHM is not detailed or accurate in the Monterey Subbasin.

The Monterey Subbasin Model focuses on conditions within the Monterey Subbasin and has incorporated over 30,000 water level measurements from the Monterey Subbasin in its calibration. It also incorporates water level data from the 180/400-Foot Aquifer Subbasin and Seaside Subbasin to establish transient boundary conditions and account for conditions in these adjoining subbasins. EKI has worked closely with M&A to incorporate feedback regarding conditions in the Corral de Tierra area and the 180/400-Foot Aquifer Subbasin.

Due to the limitations of the SVHIM in its representation of the Monterey Subbasin and the more robust calibration of the Monterey Subbasin Model for this subbasin, SVBGSA and MCWD GSA plan to use the Monterey Subbasin Model for developing the Monterey Subbasin GSP. The Monterey Subbasin Model will also form the basis for the seawater intrusion model that SVBGSA has received grant funding to develop for the Monterey Subbasin.

MODELING COLLABORATION

EKI and M&A began collaborating on modeling while developing the SGMA Round 3 Planning Grant application for the Monterey Subbasin. Based on this application, MCWD received grant funds to develop the Monterey Subbasin Model, and SVBGSA received grant funds to develop a seawater intrusion model for the Monterey Subbasin.

EKI engaged M&A during the Monterey Subbasin Model development process to review the model's layering and structure, connectivity of the aquifers, input data such as historical groundwater elevations and extractions, boundary conditions with adjacent subbasins, and calibration. EKI and M&A will continue to collaborate in the interpretation of model results.

M&A will use the Monterey Subbasin Model as the basis for the seawater intrusion model for the Monterey Subbasin. Aquifer layers in the Monterey Subbasin Model will be extended north into the 180/400 Aquifer Subbasin in a manner that is consistent with SVIHM layering and incorporate boundary conditions and flows from the SVIHM. Development of the seawater intrusion model will begin upon completion and calibration of the Monterey Subbasin Model.

Since these are grant funded, no additional funding is needed for the modeling other than consultant staff time, and both agencies will have access to both models. SVBGSA and MCWD have a collaborative working relationship.

MODEL COMPARISON

M&A has been reviewing and interrogating the SVIHM model. The SVIHM was provided in a provisional and preliminary status, meaning that the USGS can, and likely will, update and change the model prior to its release to the public. The Monterey Subbasin and Seaside Subbasin are included in the SVIHM; however, model development and calibration in these subbasins appears not to have been performed to the same degree as other areas of the Model. For example, the SVIHM did not include any water level calibration points in the Seaside Subbasin and only one calibration location in the Monterey Subbasin.

Model calibration is an assessment of how a model simulates observed historical conditions. Generally, a model's calibration is evaluated through calibration statistics – comparing simulated groundwater elevations to measured groundwater elevation data. One commonly used statistic is known as the scaled root mean squared residual of the error between simulated water levels and observed water levels. A general rule of thumb in assessing model calibration is that the model is considered adequately calibrated when the scaled root mean squared error is less than 10%. The basin-wide statistics of the SVIHM meet these criteria (see Attachment A).

In the Monterey Subbasin, the SVIHM includes only one location containing calibration data; and an assessment of the Subbasin calibration cannot be adequately performed using the limited measurements from only this one data location. To check the accuracy of the SVIHM in the Subbasin, M&A compared simulated groundwater elevations from the SVIHM to an additional 4,555 observed water levels from 55 locations in the Monterey Subbasin. With the additional data. The root mean squared error of the residuals is over 7%, which indicates reasonable calibration (see Attachment B).

However, comparing simulated and observed hydrographs across the Subbasin shows that the model results do not match measured data in many areas: particularly in the Corral De Tierra. Some hydrographs have opposite trends, indicating the model is not adequately calibrated in this area. Attachment C includes some example hydrographs that illustrate certain wells with inadequate calibration. Measured data on these hydrographs are shown with black dots, and simulated data are shown with blue lines. The clear difference between measured and simulated trends on these plots results in poor confidence in the model's ability to simulate at least parts of the Monterey Subbasin. This poor confidence only applies to the Monterey Subbasin; much of the rest of the model is well calibrated.

In the Corral de Tierra area, only the bottom three layers of the SVIHM are active. These three layers represent the bedrock (bottom layer) and part of the El Toro Primary Aquifer System (other two active layers). This model configuration raises concerns over the adequacy of hydrogeologic representation of the Corral de Tierra area.

In contrast to the SVIHM, the Monterey Subbasin Model being developed by EKI currently has a root mean squared error residual of less than 2% (Attachment D). Calibration of the Monterey Subbasin model is ongoing, and all results are still preliminary. The Monterey Subbasin Model also has more detailed and more accurate representation of the hydrogeology in the Corral de Tierra area, which was developed incorporating input from M&A. EKI has also included additional groundwater level data for calibration throughout the Monterey Subbasin, totaling 30,555 observations from 608 wells. Thus, because of the more accurate calibration and hydrogeologic representation of the Monterey Subbasin within the Monterey Subbasin Model, SVBGSA plans to use the Monterey Subbasin Model for the development of the Monterey Subbasin GSP.

MODEL COMPATIBILITY

To assess model compatibility, EKI and M&A have been collaborating on modeling and most recently have compared information from the Monterey Subbasin Model and the SVIHM. This includes analyzing conditions along the boundary of the 180/400-Foot Aquifer Subbasin and beneath the Salinas River. Groundwater levels along this boundary are being compared to ensure the two models are compatible and simulate this boundary comparably. Model layering and hydrogeologic representation have also been reviewed and appear to reasonably match. In some areas, the Monterey Subbasin Model has greater vertical resolution with more refined aquifer layers. In general, however, the Monterey Subbasin Model layer is compatible with the SVIHM layering.

In the future, when the SVIHM becomes public, the information from the Monterey Subbasin Model could be incorporated into the SVIHM. Additionally, SVBGSA could expand the seawater intrusion model into the 180/400-Foot Aquifer Subbasin by incorporating SVIHM parameters so that it can model the impacts of valley-wide projects on seawater intrusion.

CONCLUSION

A detailed description of the Monterey Subbasin Model will be included as an appendix to the Monterey Subbasin GSP, which will be made available for public review and comment. In addition, the Monterey Subbasin Model will be submitted to the California Department of Water Resources as part of the GSP. It will be available for future use by the USGS and others as part of basin-wide modeling efforts.

All groundwater models are tools to help understand groundwater conditions and how factors may change groundwater conditions. Given the complexity of groundwater interactions, models provide the best tool for understanding of these interactions and their effects. Exact numbers will change as the Model is refined and updated; however, it will not likely change the direction and approach of groundwater management.

1.0 Introduction

This monitoring plan has been developed by the Monterey County Water Resources Agency (MCWRA) to meet requirements of the California Department of Water Resources (DWR) California Statewide Groundwater Elevation Monitoring (CASGEM) program. The plan to covers monitoring of groundwater elevations within high and medium priority alluvial subbasins identified in DWR Bulletin 118 that are located in Monterey County, and for which a Monitoring Entity has not yet been designated. This monitoring plan provides information on the groundwater basins, the wells to be sampled, and the monitoring schedule and methods.

1.1 Scope and Purpose

The monitoring plan presents descriptions of the groundwater subbasins; monitoring schedule and well network distribution; procedures for collecting and reporting the groundwater elevation data; and a description of the monitoring plan rationale.

This groundwater monitoring plan can be revised as necessary when refinements are made to the monitoring network to address program needs and data gaps. Revisions will be submitted to DWR when additions or removal of wells from the monitoring network occur.

2.0 Groundwater Basin Descriptions and Hydrogeology

Monterey County is located in the Central Coast Hydrologic Region. Thirteen basins and subbasins are identified in DWR Bulletin 118 as being partially or fully located within Monterey County (Figure 1).

This monitoring plan addresses seven of the subbasins in the Salinas Valley Groundwater Basin, specifically those which DWR has prioritized as “high” or “medium” (Table 1). Three of the basins - Cholame Valley (3.5), Lockwood Valley (3-6), and Peach Tree Valley (3-32) - have been prioritized as “low” or “very low” and will be covered by a subsequent monitoring plan.

Table 1 - DWR Basin Nomenclature, Numbering, and Prioritization

Subbasin Name	Basin/Subbasin Number	Basin Prioritization
180/400 Foot Aquifer	3-4.01	High
East Side Aquifer	3-4.02	High
Forebay Aquifer	3-4.04	Medium
Upper Valley Aquifer	3-4.05	Medium
Paso Robles Area	3-4.06	High
Langley Area	3-4.09	Medium
Corral de Tierra Area	3-4.10	Medium

The remaining three basins in Monterey County - Carmel Valley (3-7), Pajaro Valley (3-2), and the Seaside Area (3-4.08) - have a designated Monitoring Entity. The Monterey Peninsula Water Management District (MPWMD) is the Monitoring Entity for the Carmel Valley and Seaside basins; Santa Cruz County Environmental Health Services is the Monitoring Entity for the Pajaro Valley basin. The Paso Robles Area will be monitored both by MCWRA and the San Luis Obispo County Flood Control & Water Conservation District, with monitoring split along the county lines.

2.1 Overall Setting

The Salinas Valley is an intermontane alluvial basin extending 120 miles southeast from the Monterey Bay to Paso Robles. Although the valley fill is as thick as 15,000 feet, all of the principal water-bearing sediments lie within 2,000 feet of the ground surface (Showalter et al, 1983). These water-bearing sediments consist of Tertiary and Quaternary marine and terrestrial sediments, including the Pliocene Purisima Formation, the Plio-Pleistocene Paso Robles Formation, the Pleistocene Aromas Formation, and the Pleistocene to Holocene Valley Fill.

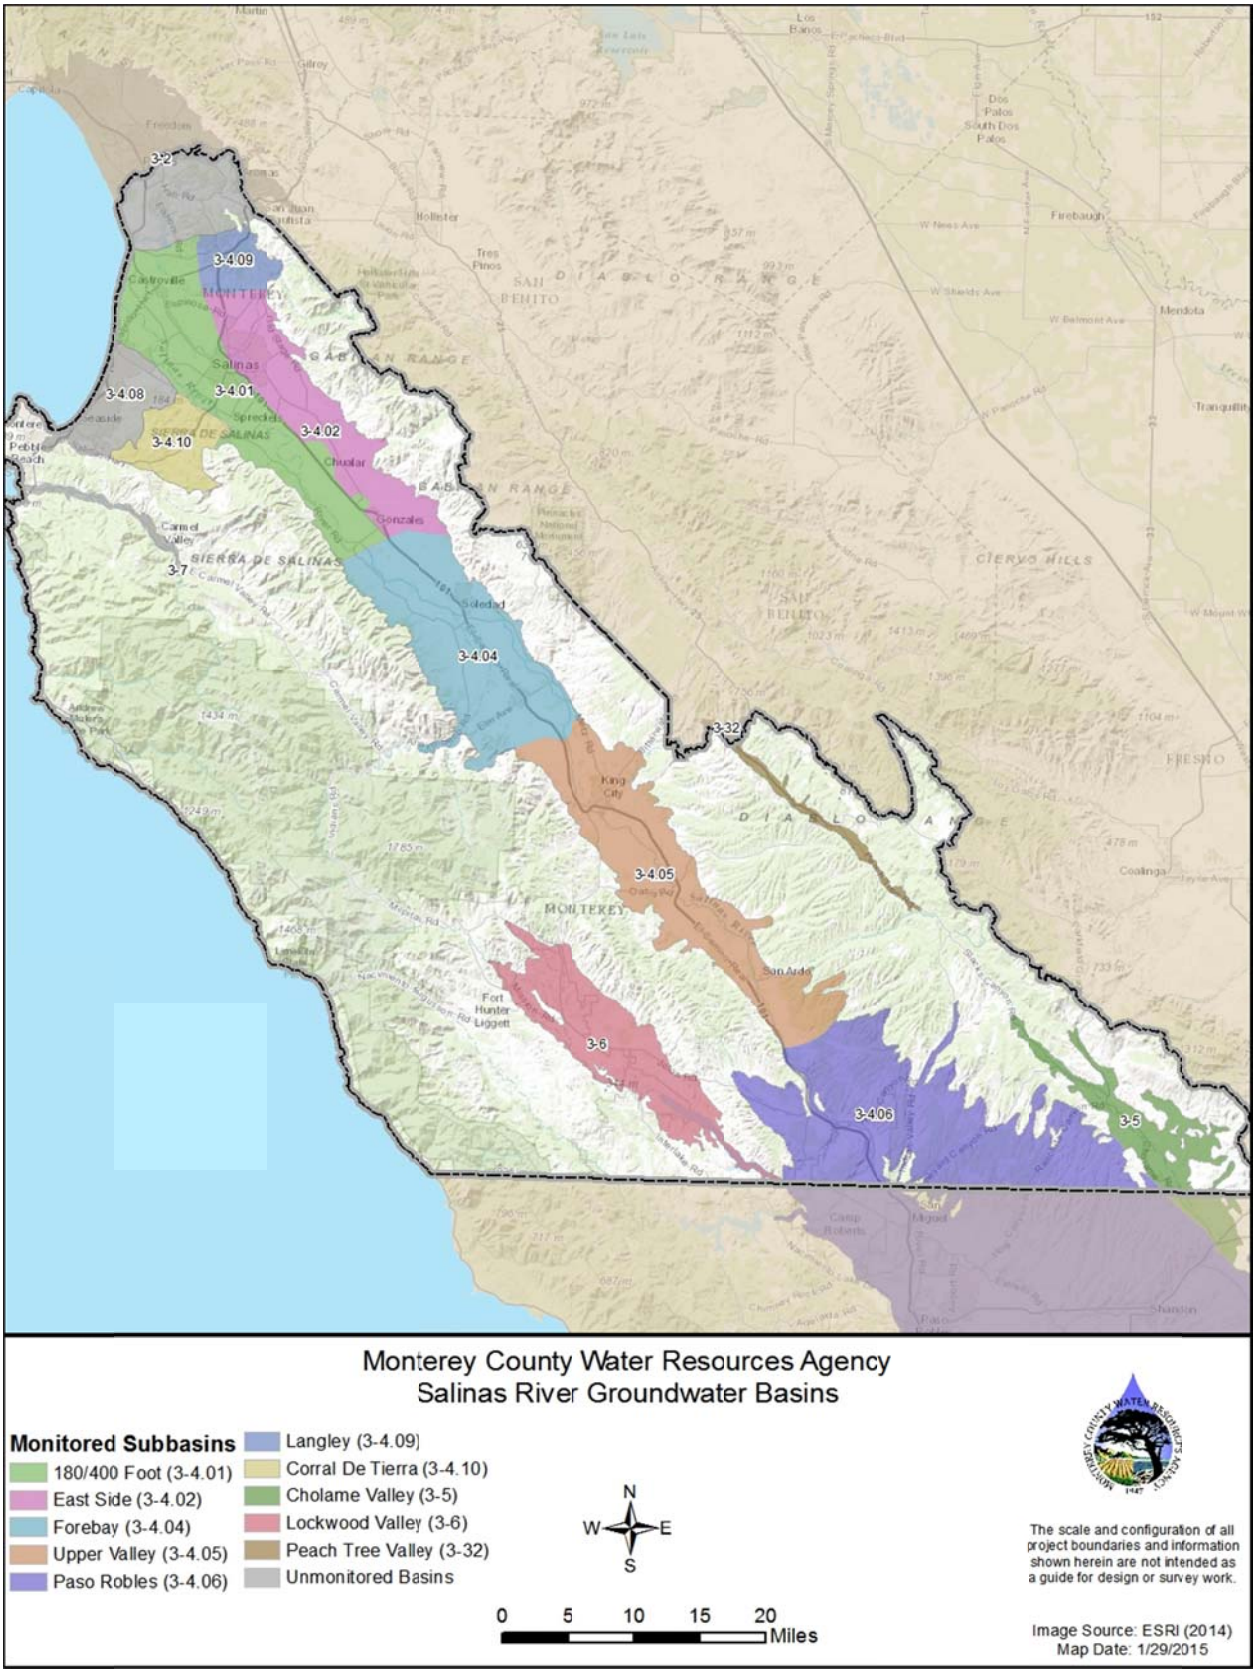
2.2 180/400 Foot Aquifer

The 180/400 Foot Aquifer subbasin is located in the northwestern part of the Salinas Valley basin. The northeastern boundary of the 180/400 Foot Aquifer subbasin is shared with the East Side Aquifer subbasin; the Forebay Aquifer subbasin lies on southeastern boundary, near the City of Gonzales. Monterey Bay abuts the northwestern boundary of the 180/400 Foot Aquifer subbasin.

The 180-Foot Aquifer ranges from 50 to 150 feet in thickness and is confined by an overlying blue clay layer, known as the Salinas Aquitard, which ranges from 25 to 100 feet thick. The Salinas Aquitard thins to the east and south of the subbasin and is present only in this subbasin. The 180-Foot Aquifer consists of interconnected layers of sand, gravel, and clay that are separated from the 400-Foot Aquifer by blue marine clay and other discontinuous aquifers and aquitards ranging from 10 to 70 feet in thickness. The 400-Foot Aquifer has an average thickness of 200 feet and consists of sands, gravels, and clay lenses (DWR, 2003). The blue marine clay aquitard has been reported to be absent in some areas of the 180/400 Foot Aquifer subbasin (Kennedy/Jenks, 2004).

There is a third water-bearing unit underlying the 180/400 Foot Aquifer subbasin, often referred to as the Deep Aquifer, which is separated from the overlying 400-Foot Aquifer by a blue marine clay aquitard (DWR, 2003). The Deep Aquifer is a confined unit that has been less developed than the 180-Foot and 400-Foot Aquifers, but wells are increasingly being drilled into this unit, so it will be included in the monitoring plan for this subbasin.

Figure 1 – Groundwater Basins and Subbasins in Monterey County



2.3 East Side Aquifer

The East Side Aquifer subbasin is located in the northeastern portion of the Salinas Valley basin, bounded by the foothills of the Gabilan Range to the northeast and Highway 101 to the southwest (Kennedy/Jenks 2004).

The East Side Aquifer subbasin is dominated by poorly bedded sequences of gravel, silt, sand, gravelly/sandy clay, and clay. In portions of the East Side Aquifer subbasin, decomposed granite is a prominent component of the sediments (Kennedy/Jenks, 2004). The primary water-bearing units of the East Side Aquifer subbasin are the same units that are present in the 180/400 Foot Aquifer subbasin. However, the near-surface Salinas Aquitard is not present in the East Side Aquifer subbasin, and the aquitard that separates the 180-Foot and 400-Foot Aquifers is less continuous in the East Side Aquifer subbasin, leading to semi-confined to unconfined conditions for much of the groundwater (DWR, 2003).

2.4 Forebay Aquifer

The Forebay Aquifer subbasin is located in the central portion of the Salinas Valley basin, bounded by the Sierra de Salinas and Gabilan Range to the west and east, respectively. The Forebay subbasin is bounded to the north by the 180/400 Foot Aquifer and East Side Aquifer subbasins. The southern boundary of the Forebay Aquifer subbasin is shared with the Upper Valley Aquifer subbasin (DWR, 2003).

Many of the same hydrostratigraphic units that comprise the 180/400 Foot Aquifer subbasin are present in the Forebay Aquifer subbasin, though the aquitard separating the two water bearing units in the northern subbasin is absent in the Forebay Aquifer subbasin. Groundwater in the Forebay Aquifer subbasin is unconfined and occurs in lenses of sand and gravel that are interbedded with massive units of finer grained material (DWR, 2003).

2.5 Upper Valley Aquifer

The Upper Valley Aquifer subbasin occupies a stretch of the Salinas Valley groundwater basin from just south of Greenfield, CA to San Ardo, CA. The northern border of the Upper Valley Aquifer subbasin is shared with the Forebay Aquifer subbasin, while the southern border is shared with the Paso Robles Area subbasin.

Groundwater in the Upper Valley Aquifer subbasin is unconfined and is derived primarily from an aquifer of unconsolidated to semi-consolidated and interbedded gravel, silt, sand, and alluvial fan and river deposits (DWR, 2003).

2.6 Paso Robles Area

The Paso Robles Area subbasin is partially located in Monterey County, though the majority of the subbasin is located in San Luis Obispo County. The Upper Valley Aquifer subbasin forms the northern boundary of the Paso Robles Area subbasin.

Groundwater in the Paso Robles Area subbasin is found in two formations: Holocene age alluvium and the Pleistocene age Paso Robles Formation. Groundwater in the fine- to coarse-grained sand, pebbles, and boulders of the alluvium is unconfined while groundwater in the Paso Robles Formation is generally confined (DWR, 2003).

The Paso Robles Groundwater Basin Computer Model (Model) has characterized flow in the basin using four vertical groundwater zones: one in the alluvium and three within the Paso Robles Formation (SLOCFCWD, 2014).

2.7 Langley Area

The Langley Area subbasin is located in the northeastern part of the Salinas Valley groundwater basin. Portions of the Langley Area subbasin are underlain by granitic bedrock that is not considered to be a viable water-bearing unit. In the remaining areas of the Langley Area subbasin, the groundwater supply is derived from shallow, well-sorted sands separated by confining layers of interbedded clays and silty clays (DWR, 2003).

A study of hydrogeology in northern Monterey County was conducted by Fugro West, Inc. (Fugro) and included most of the Langley Area subbasin. The Fugro study further divided the subbasin, as it is defined by DWR, into hydrogeologic subareas using factors such as well yields, depth to bedrock, volume of groundwater storage, and sources of recharge (Fugro, 1995). Two of the hydrogeologic subareas defined by the Fugro study are coincident with approximately 75% of the Langley Area subbasin: Highlands South and Granite Ridge (Figure 2).

The Highlands South subarea consists of saturated Aromas Sands (interbedded sands, clay, and gravel) overlying the Purisima Formation (semi-consolidated units of fine sand, clay, and silt), which has not proved a viable aquifer (Fugro, 1995). The Highlands South hydrogeologic subarea, as defined by the Fugro report, covers approximately 46% of the Langley Area subbasin.

The Granite Ridge subarea is characterized by a thin layer of Aromas Sands overlying granitic bedrock or weathered granite. Wells in the Granite Ridge subarea are typically completed in either granular materials (Aromas Sands and weathered granite); fresh granite; or other consolidated formations (Fugro, 1995). Approximately 29% of the Langley Area is coextensive with the Granite Ridge subarea.

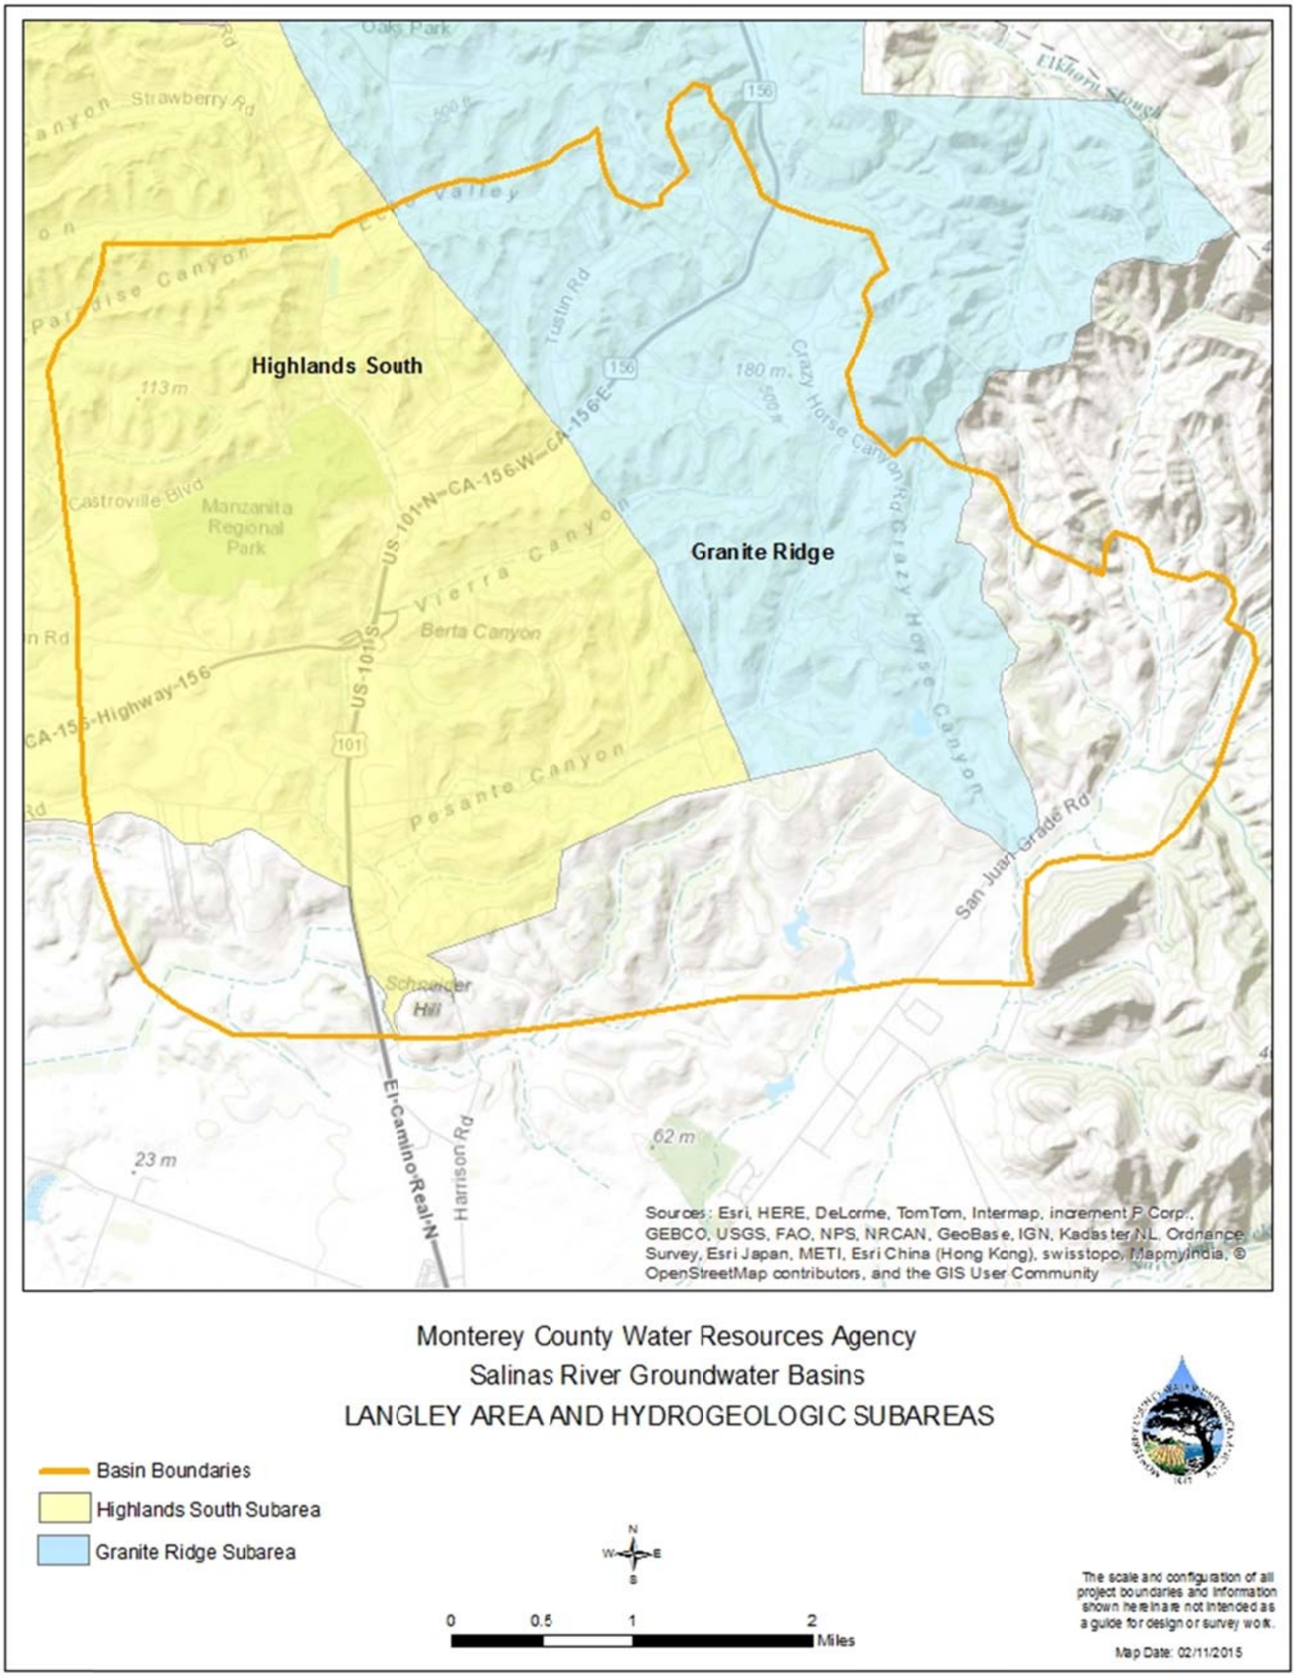
The transition between hydrogeologic conditions of the Highlands South and Granite Ridge subareas is gradual and occurs slightly east of the center of the Langley Area. The transition is characterized by the thinning of saturated sediments to the east, eventually thinning to the extent that the granitic bedrock is above regional saturation (Fugro, 1995).

2.8 Corral de Tierra Area

The Corral de Tierra Area subbasin is located to the west of the 180/400 Foot Aquifer subbasin and contains portions of the former Fort Ord and other unincorporated areas. It is bounded to the northwest by the Seaside Area subbasin.

Groundwater in the Corral de Tierra Area subbasin comes primarily from the Paso Robles Formation, which consists of sand, gravel, and clay interbedded with minor calcareous beds. The poorly consolidated marine sandstone of the Santa Margarita Formation also yields water in the Corral de Tierra Area subbasin (DWR, 2003). A previous study which included the Corral de Tierra Area found that although there are thick sequences of low permeability material in some areas of the subbasin that may limit vertical hydraulic communication between aquifer units, a comparison of water level data shows general consistency between wells screened in different units (Geosyntec, 2007).

Figure 2 – Langley Area Subbasin and Hydrogeologic Subareas



3.0 Groundwater Level Monitoring

The following sections discuss the history of groundwater level monitoring in the Salinas Valley groundwater basin; current monitoring activities in the basin; and the proposed network of CASGEM monitoring wells. Data gaps in the monitoring network are also identified and discussed.

3.1 Monitoring History

Groundwater level measurements in the Salinas Valley groundwater basin have been ongoing, in some form, since the 1940s. Presently, MCWRA conducts monthly and annual surveys of groundwater levels to monitor fluctuations in water level and determine relative changes in storage over time. Data collected through the MCWRA groundwater level monitoring program also contributes to analysis of seawater intrusion in coastal groundwater zones.

MCWRA maintains a small network of dedicated monitoring wells where groundwater level data is recorded by a pressure transducer on an hourly basis. However, the distribution of the dedicated monitoring wells is limited; much of the groundwater level data is collected from privately-owned agricultural production wells where owners have granted permission to MCWRA. MCWRA collects groundwater level measurements from over four hundred wells on an annual basis; on a monthly basis, groundwater levels are measured in about one quarter of these wells.

3.2 Monitoring Network Rationale

The CASGEM network is of a combination of dedicated monitoring wells that are owned by MCWRA and wells that are owned by private individuals who elected to participate in the CASGEM program.

The MCWRA-owned monitoring wells were selected for inclusion in the program due to their distribution throughout Monterey County, the availability of detailed and reliable well construction data, and relative ease of data collection.

In the selection of privately owned wells, preference was given to wells that are in the MCWRA monthly groundwater level monitoring program, since the minimum number of data points for CASGEM reporting are already being gathered. MCWRA also considered wells that are in the annual groundwater level monitoring program. Wells in the annual program are currently measured only once per year, so additional staff effort will be required to schedule a second visit in order to satisfy the biannual measurement criteria for CASGEM reporting.

Additional privately owned wells were sought in areas where dedicated monitoring wells are not available. MCWRA filled as many data gaps as possible with privately owned wells, working toward a target minimum density of 10 wells per 100 square miles of groundwater basin.

Approximately one third of the land in the Corral de Tierra Area is federal property. MCWRA has reached out to the United States Army Corps of Engineers (USACE), which owns the property, seeking participation in the CASGEM program (Appendix A). As of the date of this monitoring plan, USACE has not responded to MCWRA's letter. As such, the land owned by USACE is considered a data gap in the Corral de Tierra Area. The following subbasin-specific discussions address data gaps in the MCWRA CASGEM network in more detail.

MCWRA considered the availability of reliable well construction data choosing CASGEM wells. Where appropriate, wells were also selected to provide coverage of vertically distinct aquifers.

Table 2 - Recommended Monitoring Well Network Density by Subbasin

Subbasin Name	Subbasin Area in Monterey County (mi²)	Federal Land Area of Subbasin (mi²)	Wells Needed for Target Minimum Density
High and Medium Priority (10 wells per 100 mi²)			
180/400 Foot Aquifer	132	0	13
East Side Aquifer	90	0	9
Forebay Aquifer	147	0	15
Upper Valley Aquifer	153	0	15
Paso Robles Area	221	0	22
Langley Area	24	0	2
Corral de Tierra Area	35	12	4
Total wells in High and Medium Priority Subbasins			**80**

3.3 CASGEM Monitoring Network and Data Gaps

This section describes the number and distribution of wells in the CASGEM monitoring network of each subbasin, identifies data gaps in some of the monitored subbasins, and outlines the approach for addressing data gaps where applicable.

As shown in Table 3, the CASGEM network meets the target minimum density in some subbasins, while additional wells are required in other subbasins in order to meet the target.

Table 3 – CASGEM Network Compared to Target Minimum Density Numbers

Subbasin Name	Target Minimum Density	CASGEM Wells	Voluntary Wells	Wells Remaining to Meet Target Minimum Density
180/400 Foot Aquifer	13	22	1	0[a]
East Side Aquifer	9	8	0	1
Forebay Aquifer	15	9	2	11[b]
Upper Valley Aquifer	15	3	0	12
Paso Robles Area	22	1	0	21
Langley Area	2	3	0	0[c]
Corral de Tierra Area	4	2	0	2
TOTAL	**80**	**48**	**3**	**47**

Notes

(a) Additional wells will be sought to address a data gap in the vertical distribution of the well network as funding is available.

(b) Forebay Aquifer CASGEM wells include multiple well clusters, so only four geographic locations are covered by the nine wells.

(c) Additional wells will be sought to address data gaps in horizontal distribution of the well network as funding is available.

3.3.1 180/400 Foot Aquifer

The CASGEM well network for the 180/400 Foot Aquifer subbasin is shown on Figure 3. MCWRA has fifteen (15) dedicated monitoring wells in the 180/400 Foot Aquifer subbasin, all of which will be included in the CASGEM network. Some of the monitoring wells consist of clusters of multiple nested wells at a single location, with each well in the cluster monitoring a different aquifer. The CASGEM well network includes seven (7) privately owned wells; where the well owner has granted permission for MCWRA to include his/her well in the CASGEM program. There is also one (1) voluntary well in the 180/400 Foot Aquifer subbasin.

Data Gaps – Horizontal Distribution of Wells

The 180/400 Foot Aquifer subbasin is 132 square miles. Based on the target minimum density of ten (10) wells per 100 square miles, this subbasin should have 13 monitoring wells to meet the needs of the CASGEM program. MCWRA has met the target minimum density in the 180/400 Foot Aquifer subbasin with a network distributed throughout the basin, as shown in Figure 3.

Data Gaps – Vertical Distribution of Wells

As discussed in Section 2.2, the 180/400 Foot Aquifer subbasin has three distinct water-bearing zones, each separated by a blue marine clay aquitard. All three aquifers will be monitored by the wells in the CASGEM network, as shown in Table 4.

Table 4 - Vertical Distribution of Wells in 180/400 Foot Aquifer

Aquifer Zone	Dedicated Monitoring Wells	Privately Owned CASGEM Wells	Total Wells
180-Foot Aquifer	8	1	9
400-Foot Aquifer	3	5	8
180/400 Foot Aquifers	4	0	4
Deep Aquifer	0	1	1
TOTAL	**15**	**7**	**22**

As shown in Table 4, eight (8) of the MCWRA dedicated monitoring wells are constructed with screens in the 180-Foot Aquifer, as is one (1) of the privately owned wells. Three (3) of the MCWRA monitoring wells are constructed with screens in the 400-Foot Aquifer, as are five (5) of the privately owned wells. Groundwater elevations in the Deep Aquifer will be monitored at one (1) well location where permission has been granted by the well owner.

Two sets of the MCWRA dedicated monitoring wells (four total wells) are constructed in areas recognized as hydrogeologic transition zones between the 180/400 Foot Aquifer and the East Side Aquifer, and between the 180/400 Foot Aquifer and the Forebay Aquifer. The transition zone between the 180/400 Foot Aquifer and the East Side Aquifer is distinguished by a shift from predominantly fluvial facies, common to the 180/400 Foot Aquifer, to predominately alluvial fan facies (Kennedy/Jenks, 2004). The transition from the 180/400 Foot Aquifer to the Forebay Aquifer is characterized by thinning and/or pinching out of the near surface confining unit, the Salinas Aquitard (DWR, 2003).

Although the site-specific geology at these monitoring wells suggests that the wells are more representative of the East Side Aquifer or Forebay Aquifer, MCWRA has assigned these four wells to the 180/400 Foot Aquifer subbasin because they are geographically located in this basin, as directed by DWR (staff communication, 2015). If an opportunity arises in the future to adjust the groundwater basin/subbasin boundaries, wells like these will be useful for defining transitional zones and aligning basin boundaries with known hydrogeology.

Though MCWRA has met the target minimum density in the 180/400 Foot Aquifer, there is only one well monitoring the Deep Aquifer Zone, which suggests a data gap in the CASGEM network. MCWRA will address this data gap by evaluating the possibility of including new privately owned wells in the CASGEM program, and will reach out to well owners seeking participation when an appropriate well is found. Additionally, while there are no funds accessible at present to drill new monitoring wells, MCWRA will consider this option if funding becomes available.

3.3.2 East Side Aquifer

The CASGEM network for the East Side Aquifer subbasin is shown on Figure 4. MCWRA has two (2) dedicated monitoring wells in the East Side Aquifer subbasin, both of which will be included in the CASGEM network. The CASGEM well network also includes six (6) privately owned wells in the East Side Aquifer subbasin.

Data Gaps – Horizontal Distribution of Wells

The East Side Aquifer subbasin has an approximate area of 90 square miles, suggesting that the subbasin should have nine (9) monitoring wells to meet the CASGEM program target minimum density. The CASGEM network in this monitoring plan, which consists of eight (8) wells, is one well short of this target minimum density.

There remains an area in the central portion of the subbasin of approximately 26 square miles (29% of the subbasin area) where there are no monitoring wells. MCWRA continues to seek suitable privately owned wells in this area for inclusion in the CASGEM program. Additionally, as funding opportunities become available, MCWRA will consider the installation of new monitoring wells in this area of the East Side Aquifer subbasin.

Data Gaps – Vertical Distribution of Wells

Groundwater in the East Side Aquifer is semi-confined to unconfined, as discussed in Section 2.3 of this document. For purposes of monitoring in this subbasin, MCWRA distinguishes the unconfined (shallow) portion of the aquifer from the semi-confined (deeper) portion, though there is not a continuous confining layer present at all locations within the subbasin.

Recognizing this distinction, the East Side Aquifer CASGEM network includes wells that are screened in both unconfined and semi-confined water-bearing zones: two (2) of the wells are screened in the shallow zone and one (1) is screened in the deeper zone.

Five (5) of the wells in the CASGEM network have screens in both zones. These wells have been included in the CASGEM network because there are few MCWRA program wells (i.e. potential CASGEM wells) in this subbasin that are screened in a discrete aquifer zone. Despite having screened intervals in both the shallow and deep zones, viable groundwater elevation data can be gleaned from these wells. Trends in the groundwater elevation data from these dual-screened wells is compared to that from wells that are screened in a discreet zone, and professional judgment is used to determine which zone is best represented by the dual-screened well and how the data fits with overall data trends seen in other wells across the basin.

MCWRA will evaluate the possibility of including additional privately owned wells, including ones that may not currently be in a monitoring program, to resolve data gaps in the East Side Aquifer. Preference will be given to wells that are screened in a single water-bearing zone. As funding becomes available, the option to install new monitoring wells will also be considered.

3.3.3 Forebay Aquifer

The CASGEM network for the Forebay Aquifer subbasin is shown on Figure 5. MCWRA has nine (9) dedicated monitoring wells in the Forebay Aquifer subbasin, all of which will be included in the CASGEM network. The nine (9) monitoring wells cover four (4) geographic locations within the basin, divided as follows: three (3) clusters of two (2) nested wells each and one (1) cluster of three (3) nested wells. The Forebay Aquifer subbasin also includes two (2) voluntary wells.

Data Gaps – Horizontal Distribution of Wells

The Forebay Aquifer subbasin is approximately 147 square miles, indicating a need for 15 monitoring wells in order to achieve the target minimum density. For the purposes of horizontal distribution, the CASGEM network in the Forebay Aquifer subbasin will cover four (4) locations due to the nested construction at some of the monitoring well pairs. An additional 11 wells are required to meet the target minimum density for this subbasin.

MCWRA does not currently have funding to support installation of an additional 11 monitoring wells in the Forebay Aquifer subbasin. However, as funding opportunities become available, MCWRA will review the possibility of installing additional wells to address data gaps in the CASGEM network. In the meantime, MCWRA will continue to evaluate existing privately owned wells and, as deemed appropriate, entreat the permission of the well owners for inclusion of more wells into the CASGEM network.

Data Gaps – Vertical Distribution of Wells

The Forebay Aquifer is considered to be an unconfined aquifer. As such, there are no data gaps in the vertical distribution of the CASGEM network. The current wells, and any additional wells that may be incorporated in the future, will be monitoring the same vertical water-bearing zone.

3.3.4 Upper Valley Aquifer

The CASGEM network for the Upper Valley Aquifer subbasin is shown on Figure 6. The CASGEM network will include the three (3) wells: one (1) dedicated monitoring well owned by MCWRA in the Upper Valley Aquifer subbasin and two (2) privately owned wells.

Data Gaps – Horizontal Distribution of Wells

The Upper Valley Aquifer subbasin is 153 square miles; therefore, 15 monitoring wells are required to meet the target minimum density for the subarea. To meet this target, the Upper Valley Aquifer subbasin will require an additional 12 wells.

MCWRA does not currently have plans or funding to install any additional monitoring wells in the Upper Valley Aquifer subbasin to alleviate the data gap in this subbasin. However, should funding become available, MCWRA will explore the installation of dedicated monitoring wells where data gaps exist in the CASGEM network. Until such funding becomes available, MCWRA will seek additional participation from private well owners whose wells are deemed suitable to achieve the needs of the CASGEM program.

Data Gaps – Vertical Distribution of Wells

The Upper Valley Aquifer is considered to be an unconfined aquifer. As such, there are no data gaps in the vertical distribution of the CASGEM network. The current wells, and any additional wells that may be incorporated in the future, will be monitoring the same vertical water-bearing zone.

Figure 3 – 180/400 Foot Aquifer Subbasin

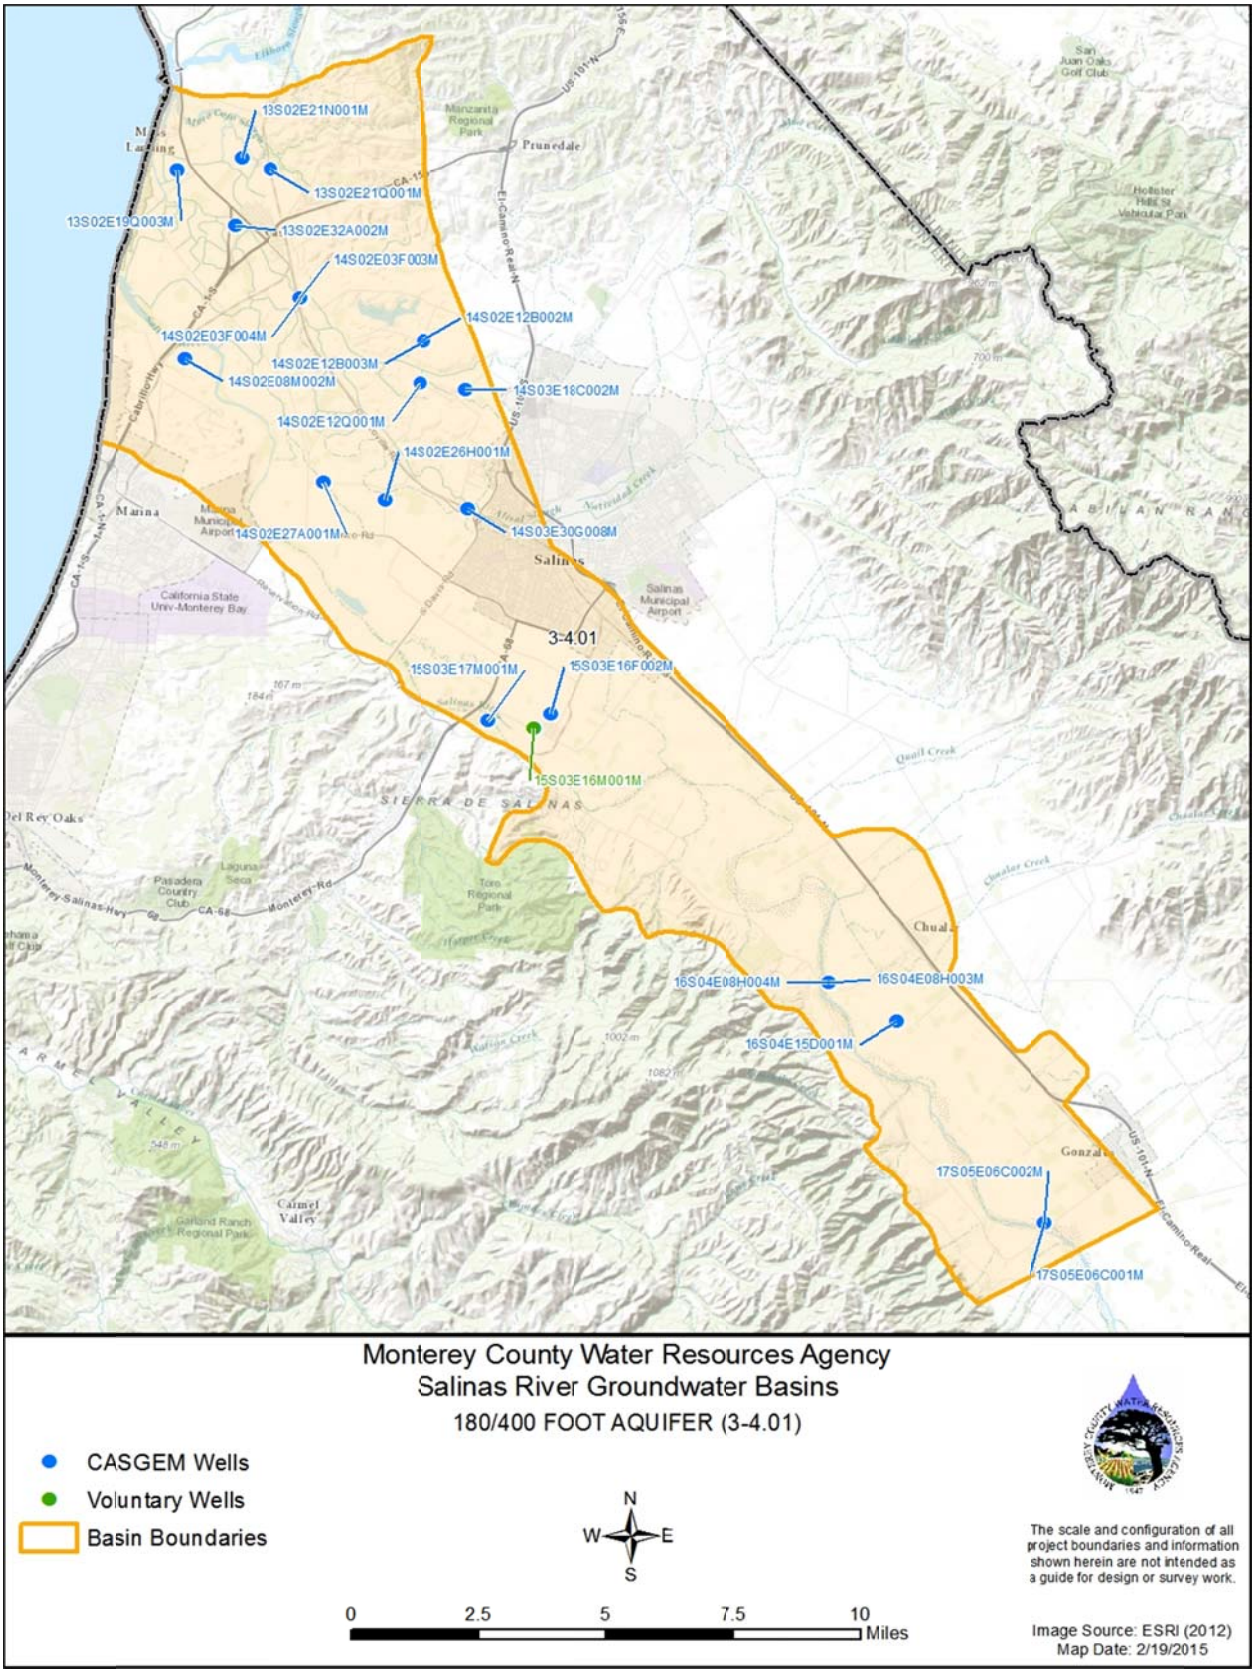


Figure 4 – East Side Aquifer Subbasin

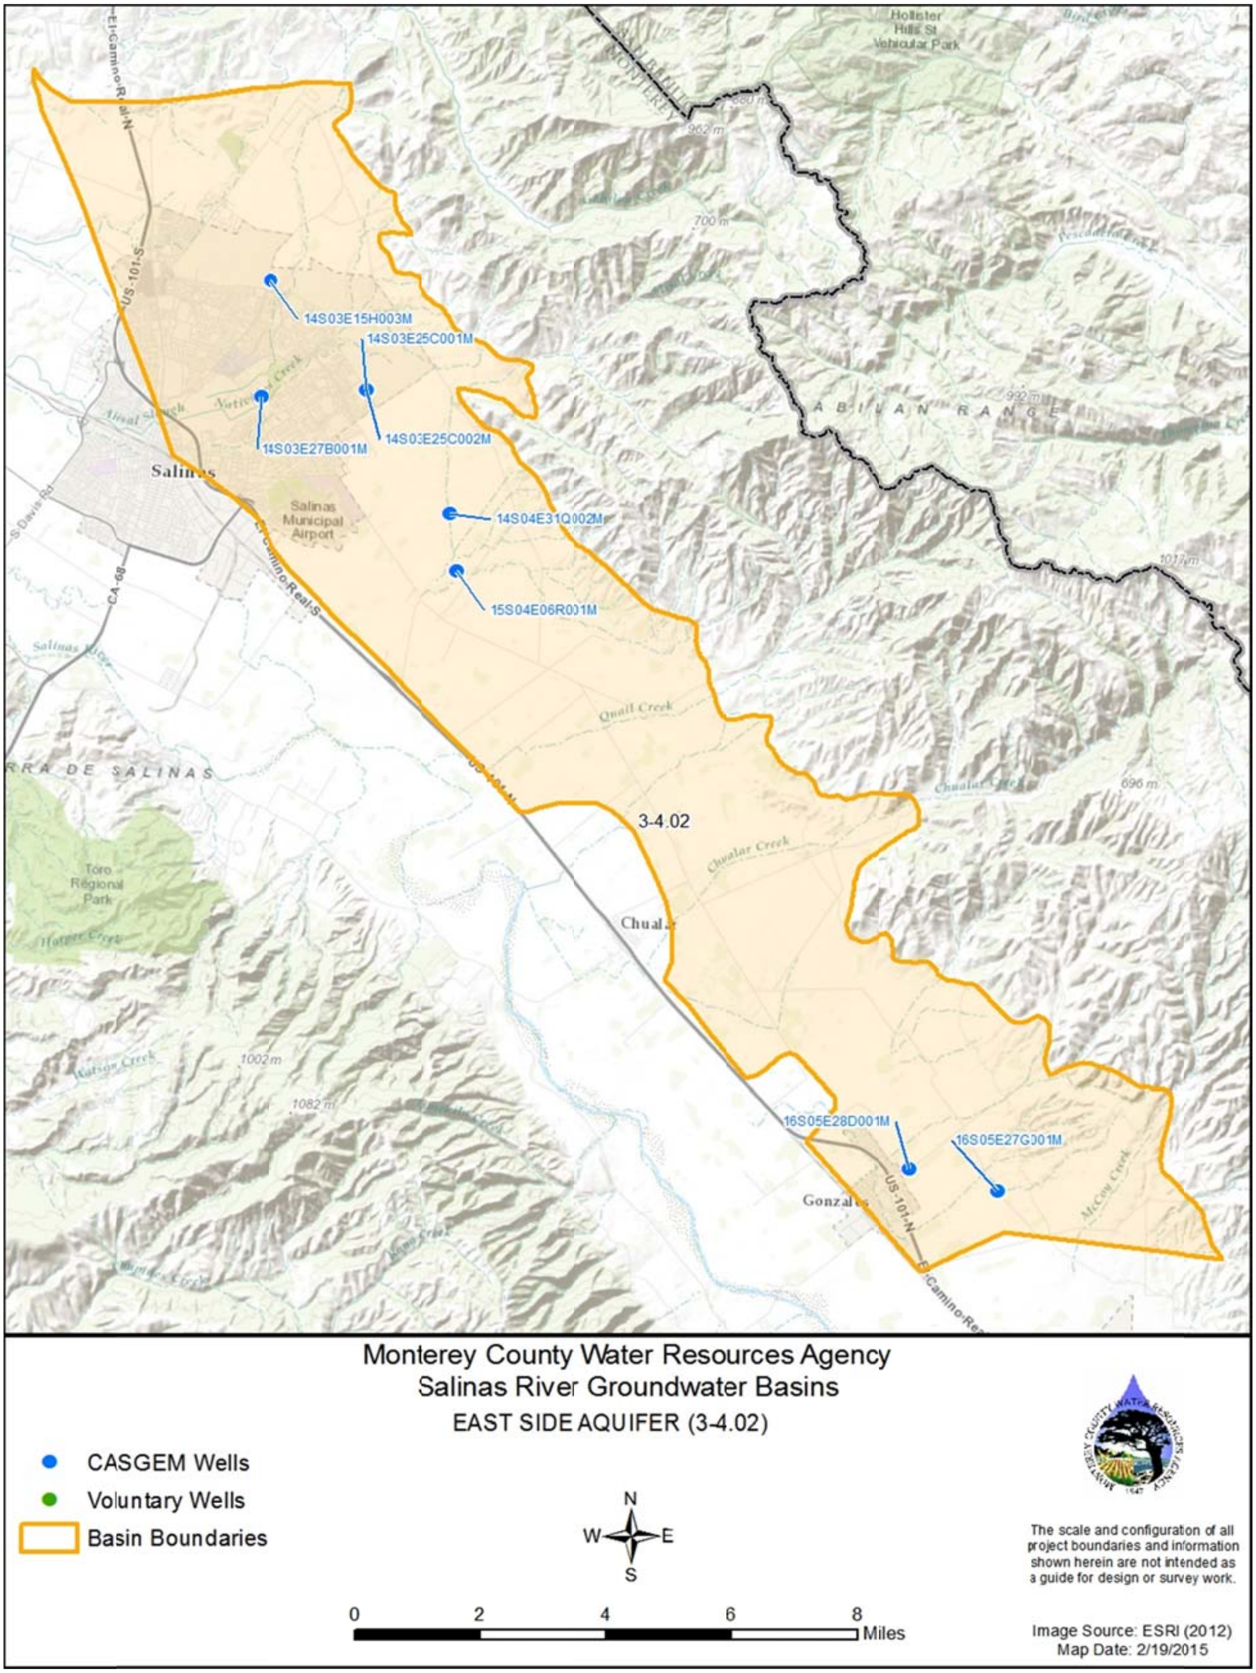

Figure 5 – Forebay Aquifer Subbasin

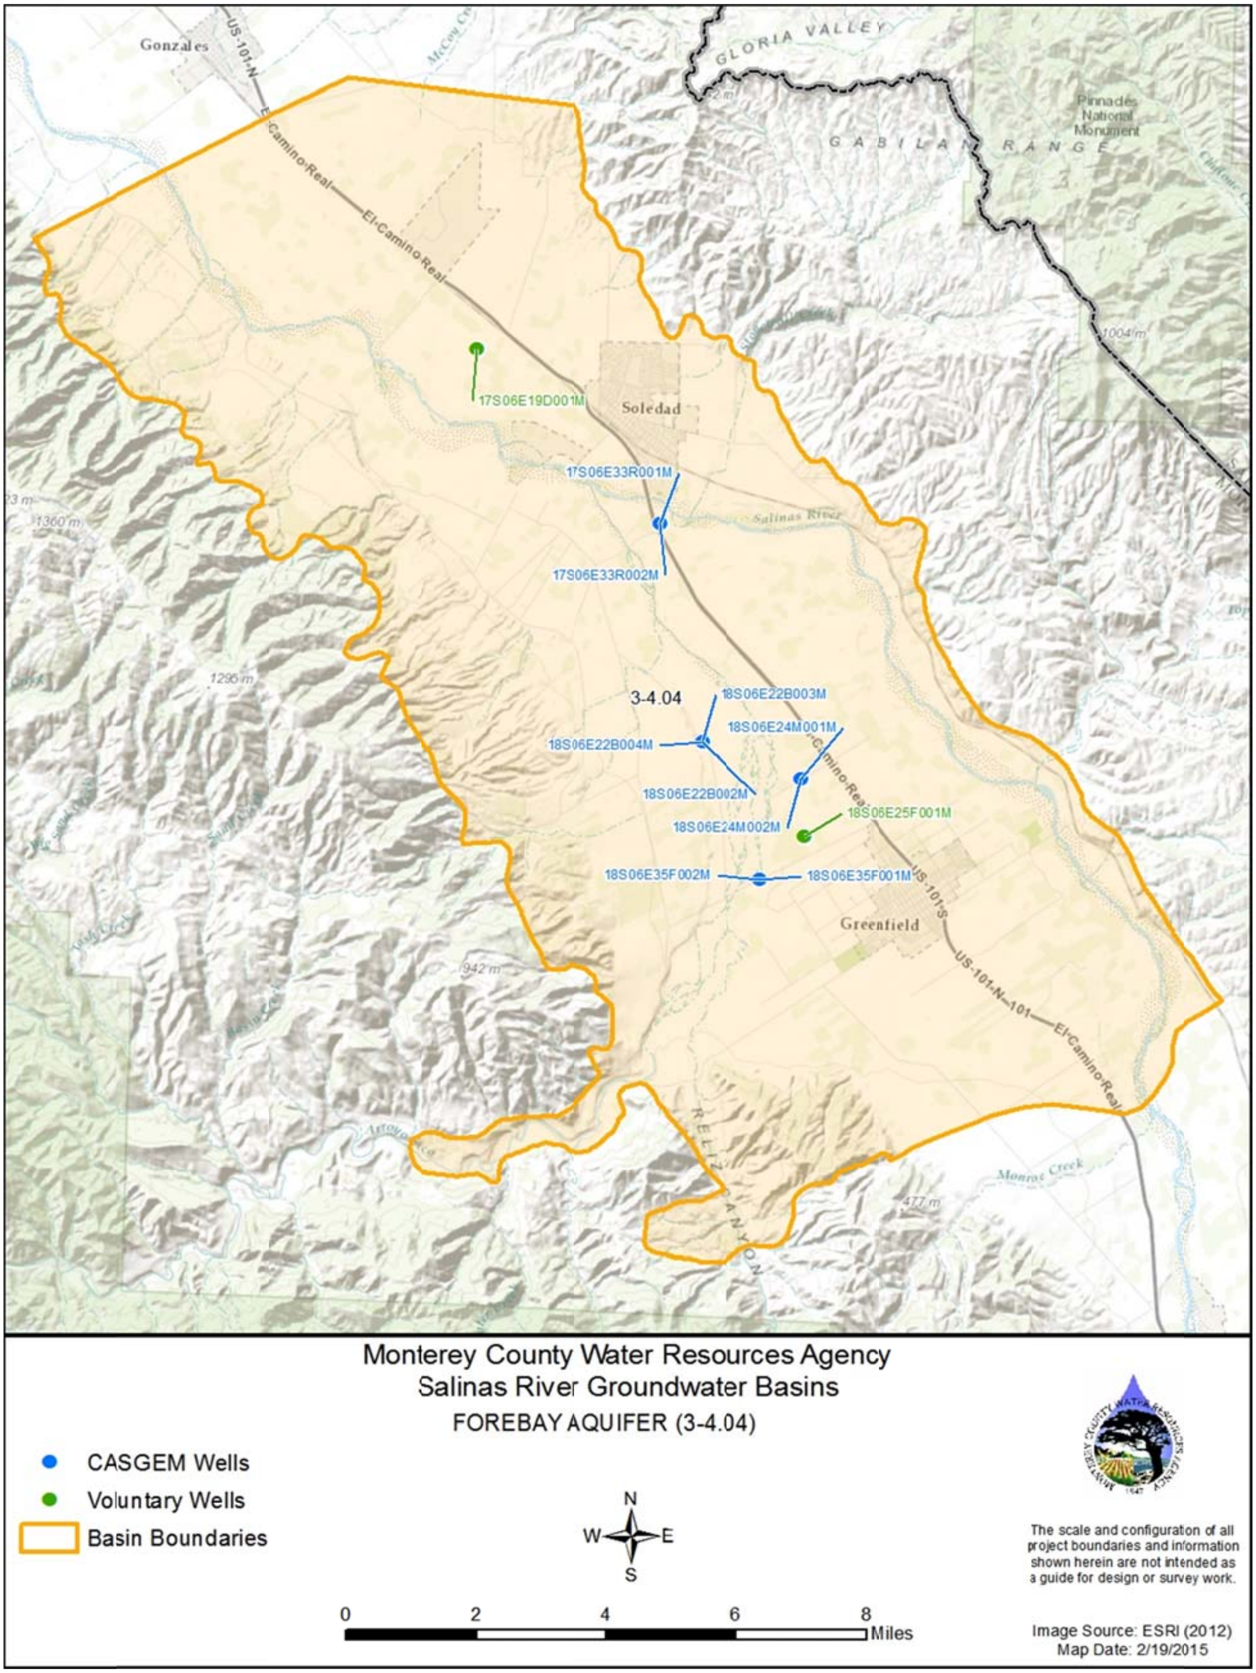

Figure 6 – Upper Valley Aquifer Subbasin

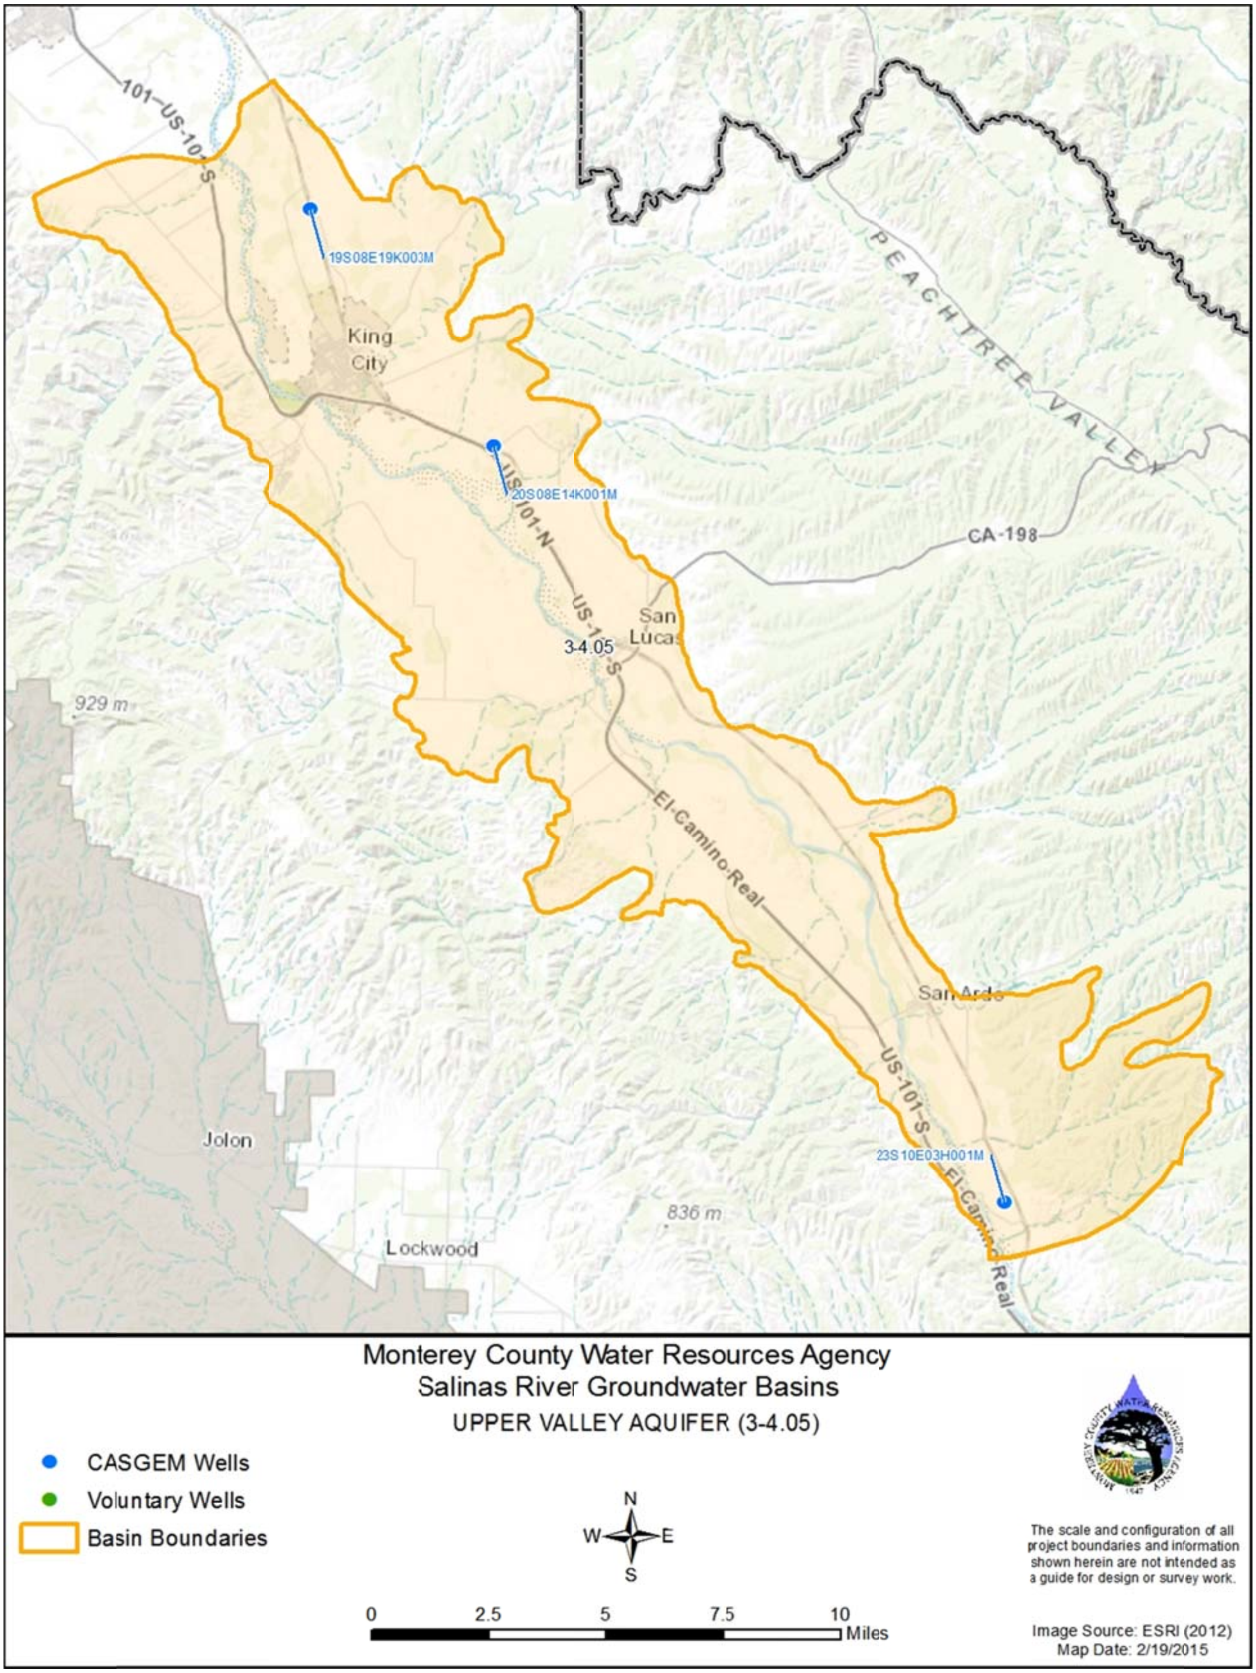

3.3.5 Paso Robles Area

The Paso Robles Area subbasin is located in both Monterey and San Luis Obispo counties, as shown on Figure 7. The subbasin is split by the county lines, with approximately 221 square miles of the Paso Robles Area located in Monterey County. Based on the area within Monterey County, 22 monitoring wells would be required to meet the target minimum density for the subarea. The remainder of the Paso Robles Area subbasin will be monitored by the San Luis Obispo County Flood Control & Water Conservation District.

MCWRA has one (1) dedicated monitoring well in the Paso Robles Area subbasin, which will be included in the CASGEM network (Figure 7). The San Luis Obispo County portion of the Paso Robles Area is currently monitored by fourteen (14) wells, as shown on Figure 7 (SLOCFCWD, 2014); one of these wells is very close to the Monterey County/San Luis Obispo County line.

MCWRA does not currently have plans or funding to install any additional monitoring wells in the Paso Robles Area Subbasin, though if funding becomes available, the construction of new monitoring wells will be explored as a mechanism for addressing this data gap in the CASGEM network. Consideration will be given to the San Luis Obispo County CAGSEM network when evaluating installation of new wells or incorporation of privately owned wells from the subbasin in the CASGEM network, as it is monitoring of the basin a whole that is the priority.

Data Gaps – Horizontal Distribution of Wells

With only one well located in the Paso Robles Area, there is a data gap to address in this subbasin; 21 additional wells are required to meet the target minimum density. MCWRA will continue to investigate the possibility of locating privately owned wells for the CASGEM program, while also considering the installation of additional monitoring wells should a funding mechanism become available. As discussed above, the existing CASGEM network in the San Luis Obispo County portion of the subbasin will be considered when evaluating augmentation of the monitoring network in the Monterey County portion of the subbasin.

Data Gaps – Vertical Distribution of Wells

As discussed in Section 2.6 of this Monitoring Plan, the Paso Robles Groundwater Basin Computer Model (Model) has characterized flow in the basin using four vertical groundwater zones: one in the alluvium and three within the Paso Robles Formation (SLOCFCWD, 2014).

The one (1) monitoring well that currently comprises the CASGEM network in this subbasin is monitoring the unconfined alluvial unit. Any future wells that are brought into the CASGEM program will be evaluated and selected with consideration given to the zone that is monitored by the well. Similarly, any new monitoring wells that may be installed in this area will be designed such that all of the zones defined by the Model are monitored.

3.3.6 Langley Area

The Langley Area subbasin is approximately 24 square miles in area. Based on the target minimum density, the CASGEM network for this subbasin should include two (2) wells. MCWRA does not have any dedicated monitoring wells in the Langley Area subbasin, but three (3) CASGEM wells have been located for this subbasin (Figure 8).

Data Gaps – Horizontal Distribution of Wells

The three (3) CASGEM wells in the Langley Area are located in the eastern half of the subbasin, leaving a data gap in the western portion of the subbasin, near the boundary with the 180/400 Foot Aquifer subbasin. MCWRA has identified possible privately owned wells that are located in the data gap area and continues to work with the well owners toward inclusion of these wells in the CASGEM program. In addition, should funding become available, MCWRA will consider this area as a candidate for installation of new monitoring wells.

Data Gaps – Vertical Distribution of Wells

The dominant water-bearing unit in the Langley Area is the Aromas Red Sands. Based on the depth of the CASGEM wells, the Aromas Red Sands are being monitored, so there are no apparent vertical data gaps to address. Other geologic units present in the Langley Area are neither alluvial nor considered to be water-bearing.

3.3.7 Corral de Tierra Area

The Corral de Tierra subbasin is approximately 35 square miles in area, so four (4) monitoring wells are required to meet the target minimum density for the subarea. MCWRA does not have any dedicated monitoring wells in the Corral de Tierra subbasin; however, MCWRA has identified two (2) CASGEM wells in this subbasin (Figure 9).

Data Gaps – Horizontal Distribution of Wells

Land that is part of the former Fort Ord, now owned by the United States Army Corps of Engineers (USACE), occupies the northwestern, and part of the northeastern, areas in the Corral de Tierra Area subbasin. MCWRA has contacted USACE seeking their participation in the CASGEM program, but has yet to receive a response (Appendix A). MCWRA cannot access the USACE land, therefore, the CASGEM network will be limited to the eastern/southeastern areas of the subbasin. The two (2) CASGEM wells are located in the south-central part of the Corral de Tierra Area, leaving a data gap in the eastern part of the subbasin.

Though MCWRA does not currently have funding to install any additional monitoring wells in the Corral de Tierra Area subbasin, this will be explored as a possibility if funding becomes available. MCWRA has been unable to secure approval for participation from the well owners contacted in this portion of the subbasin, but staff continues to look for privately owned wells and will assess the feasibility of incorporating such wells into the CASGEM network as a means of addressing data gaps. In addition, MCWRA will coordinate with USACE if that agency becomes willing to allow access to wells on the federal land at some point in the future.

Data Gaps – Vertical Distribution of Wells

Previous studies indicate that there is no significant limitation on vertical communication between the two water-bearing units in this subbasin and that wells screened in both units exhibit similar water levels (Geosyntec, 2007). Any additional wells added to the network to address horizontal data gaps will simply enhance monitoring of the same units.

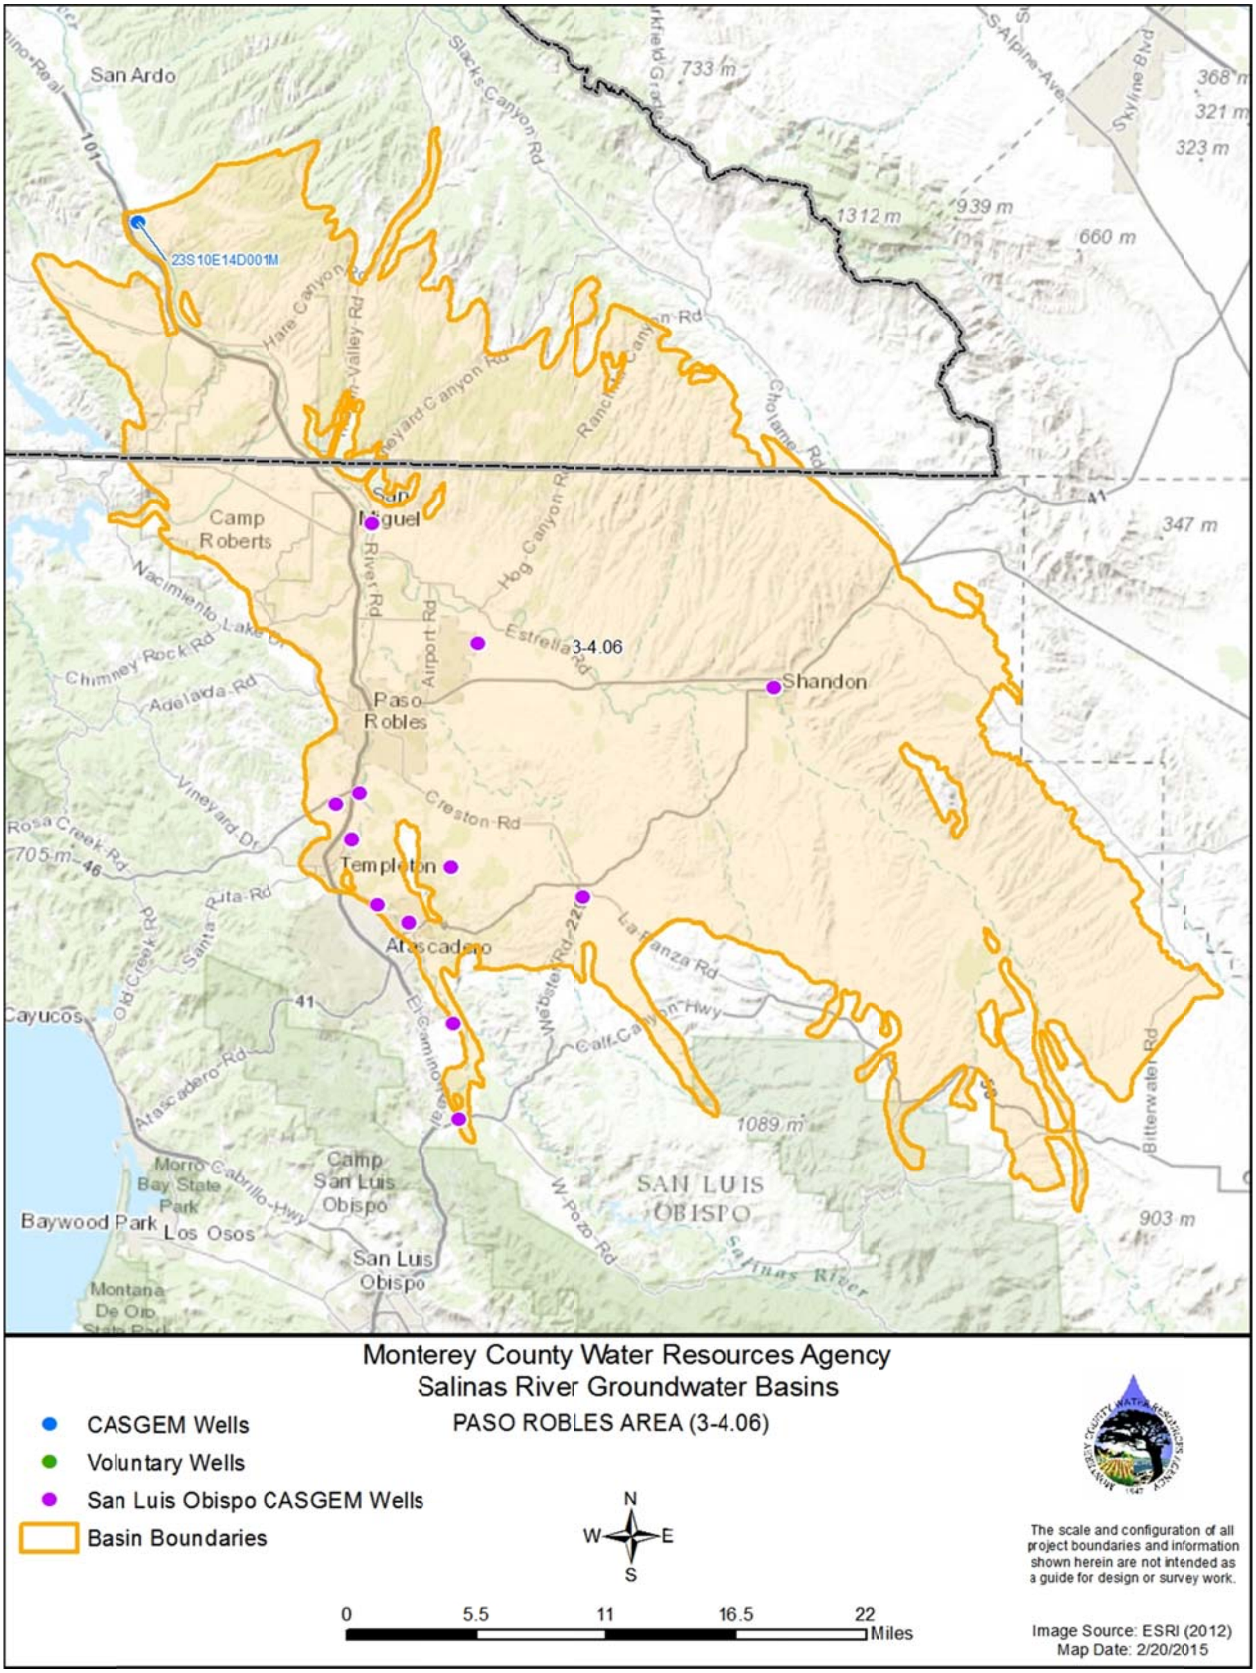

Figure 8 – Langley Area Subbasin

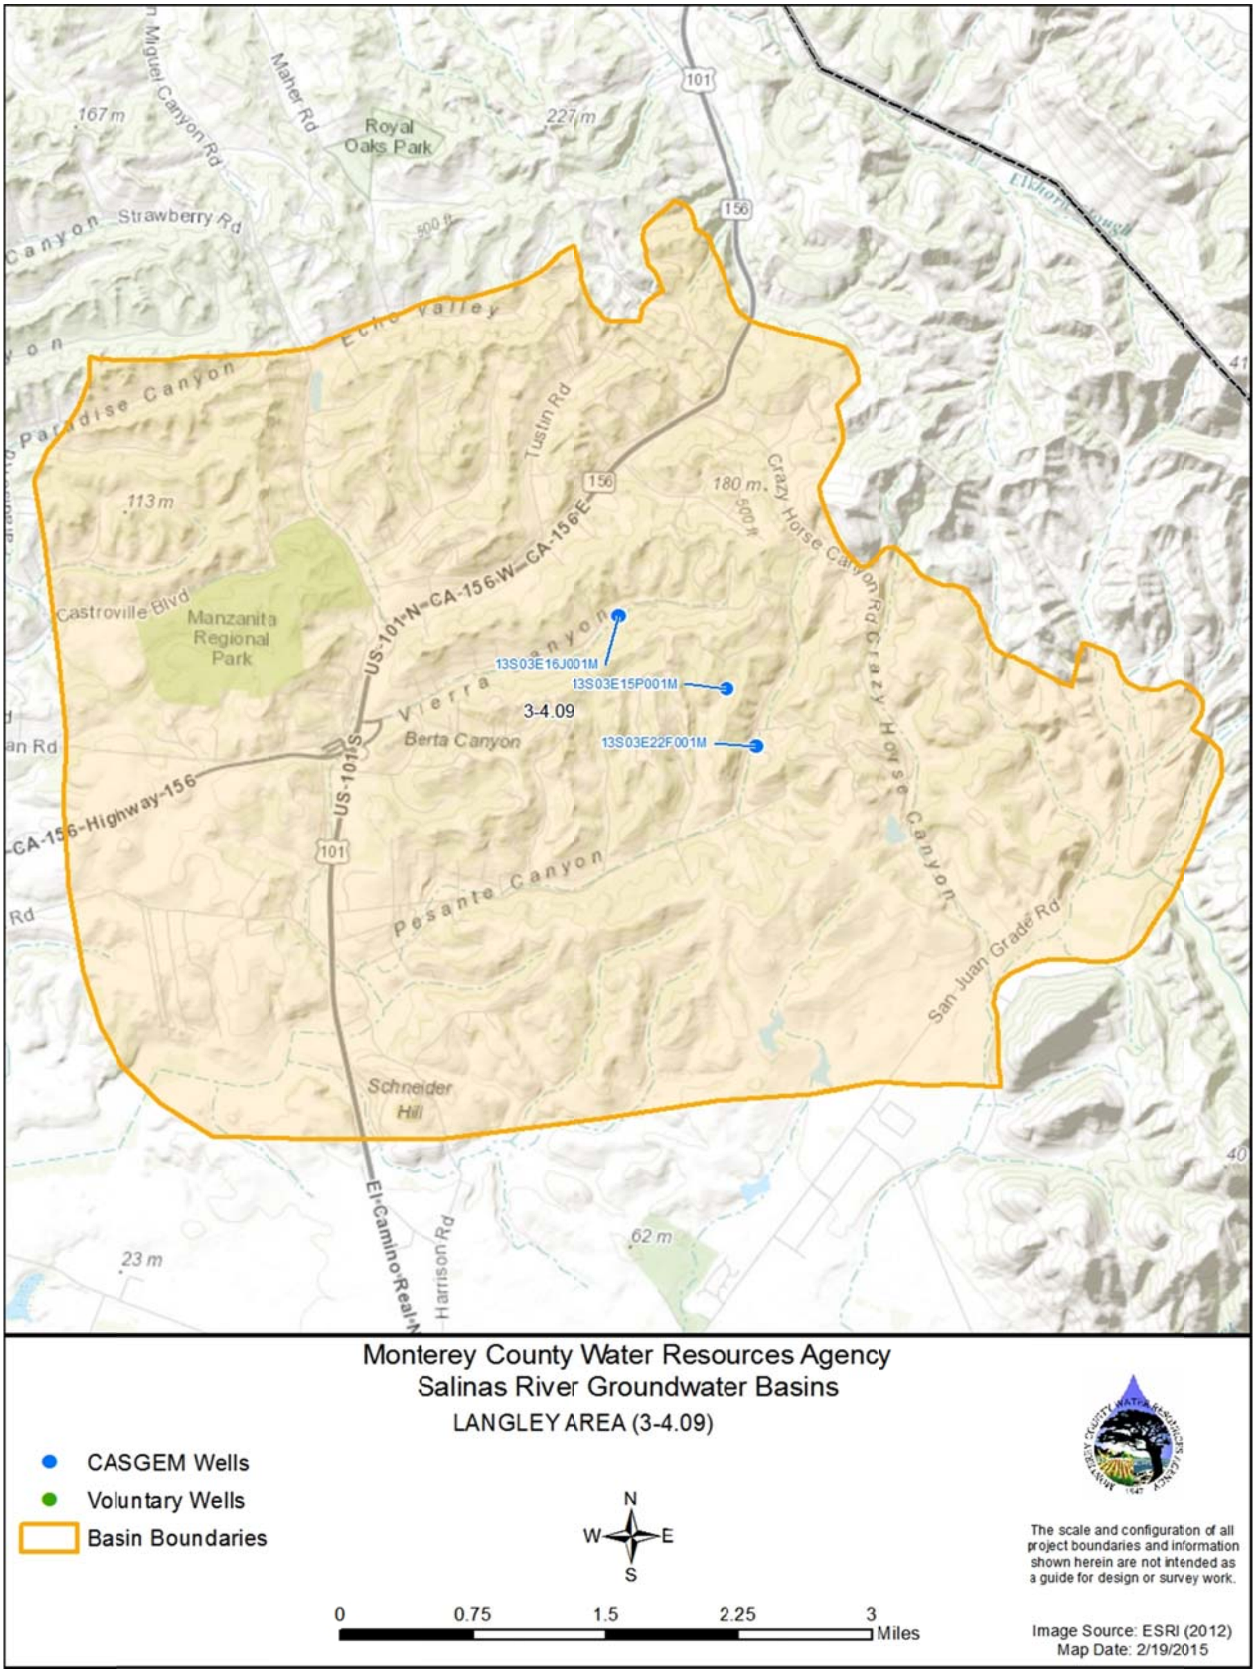

Figure 9 – Corral de Tierra Area Subbasin

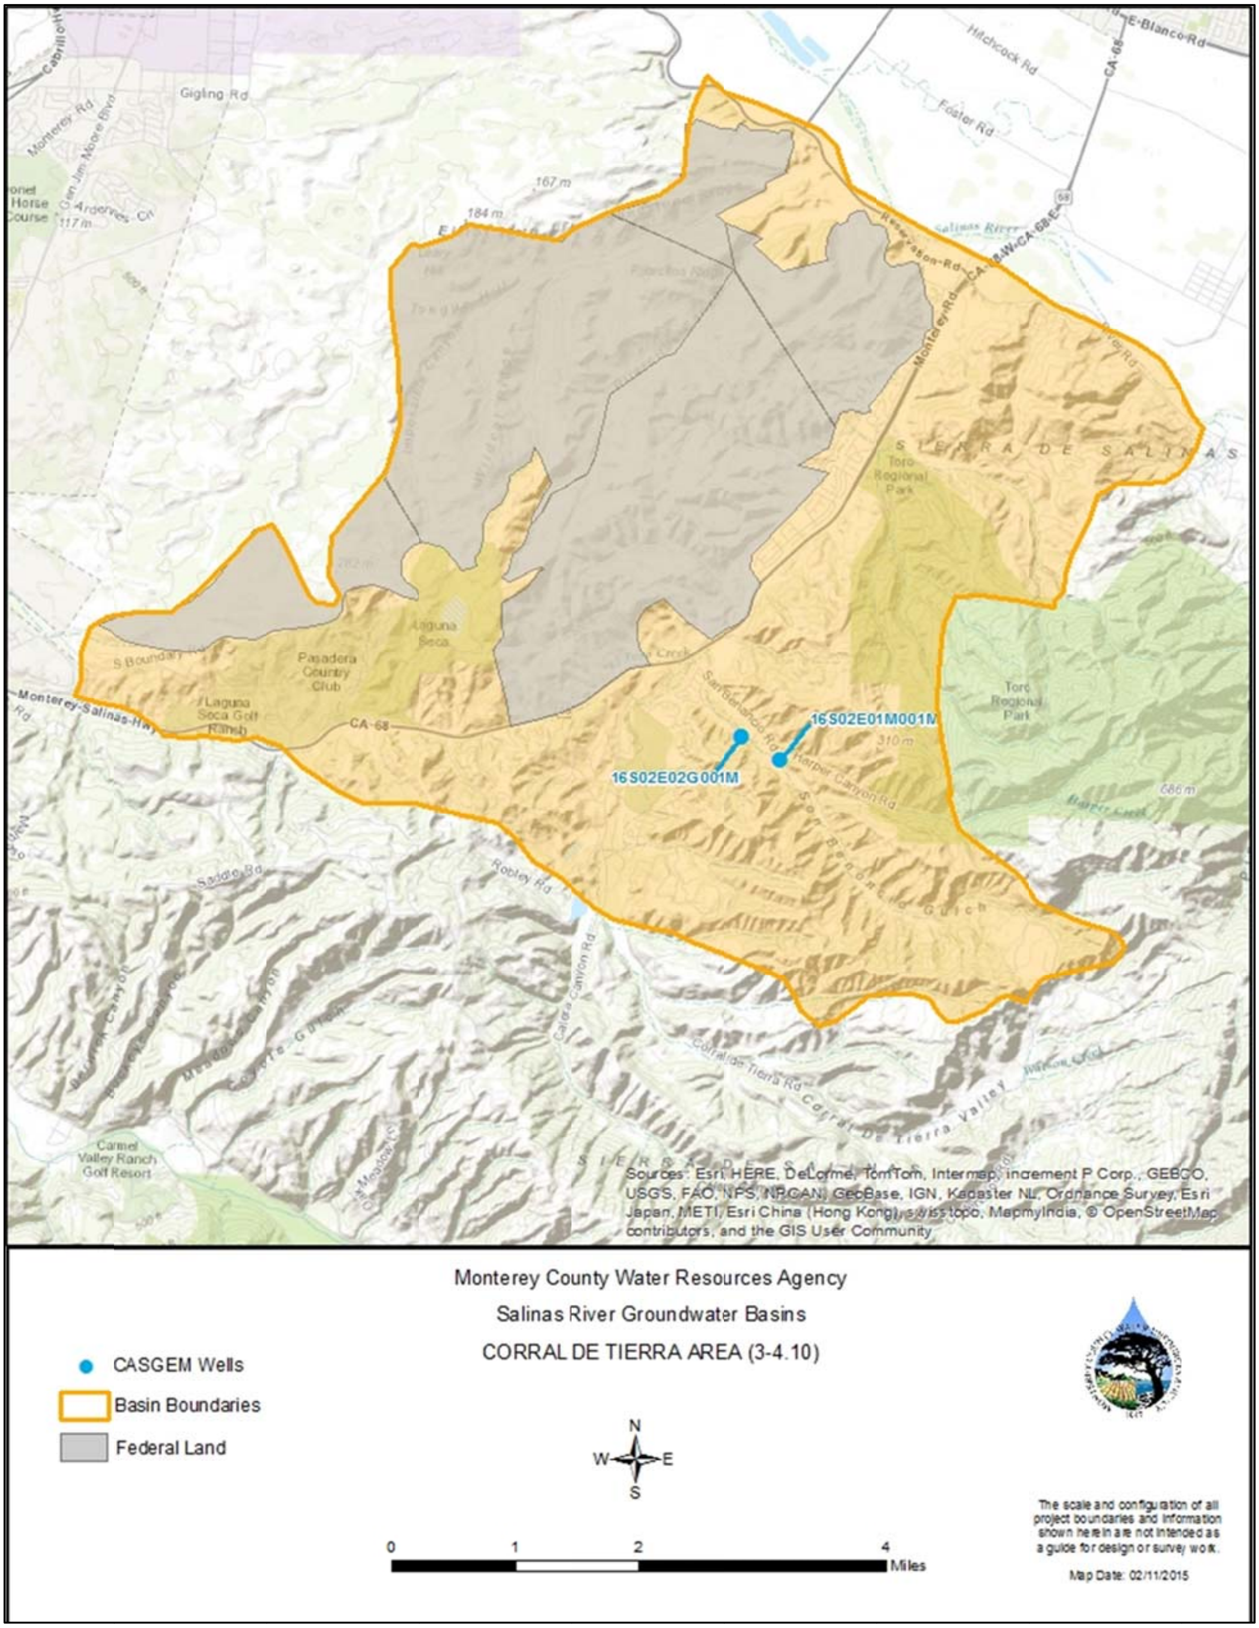

4.0 Monitoring Procedures

This section addresses the various procedures and protocols involved in collecting, processing, and reporting data from wells in the CASGEM network.

4.1 Monitoring Frequency and Timing

Nineteen (19) of the CASGEM wells are currently, and will continue to be, measured on a monthly basis. The three (3) voluntary wells are also measured monthly. MCWRA will use the monthly measurements from August and either January, February, or March to satisfy the biannual CASGEM reporting criteria.

To determine the monthly distribution of seasonal high and low groundwater elevations, MCWRA analyzed measurements from approximately 50 wells throughout the Salinas Valley Groundwater Basin. This included wells in the 180/400 Foot Aquifer, East Side Aquifer, Forebay Aquifer, and Upper Valley Aquifer. The measurements were collected during eight (8) different Water Years (WY): WY 1985, representative of near normal conditions; WY 1991, representative of dry conditions; and the six most recent Water Years, WY 2009 through WY 2014. MCWRA reports this data on a quarterly basis; a sample report is included in Appendix B.

Based on this analysis of historical data, August is typically representative of seasonal low conditions (Figure 10). A relaxation of groundwater levels, or seasonal high conditions, is evident during the period from January to March (Figure 11). Data from these three months will be evaluated and the highest groundwater elevation from that series will be submitted to the CASGEM online submittal system. The month chosen to be representative of the seasonal high groundwater conditions will be consistent across all data groups.

Nineteen (19) of the CASGEM wells are equipped with pressure transducers which collect depth to water data on an hourly basis. This data will be synthesized so that biannual measurements representing seasonal high and low conditions are available for CASGEM reporting. The groundwater level measurement collected at noon on the fifteenth day of the month will be selected and compared to other monthly data to ensure that it is a representative value. Data from the month of August will be used to represent the seasonal low and a fall/winter measurement from either January, February, or March will be used to represent the seasonal high; the same month will be used as was selected based on monthly well measurements, as discussed above.

Four (4) of the wells in the CASGEM network are currently measured once per year, during the period from November to January. Based on the recent analysis of seasonal groundwater highs, this period will be shifted to cover the months from January through March. An additional measurement event will be added during the month of August for these wells in order to also capture the seasonal groundwater low.

Appendix C contains a summary of the frequency and timing of measurement of wells in the CASGEM network. Any new wells that are brought into the CASGEM program will be monitored on a biannual basis, with data collection occurring on the same schedule as the other wells that are measured twice a year.

4.2 Well Locations

The latitude and longitude of each well was collected using a handheld GPS unit, which has accuracy to within one (1) meter. Coordinates for wells in the CASGEM network are shown in Appendix A. Any wells incorporated into the CASGEM network in the future will be geographically located using a similar method.

4.3 Reference Points

All of the wells that comprise the CASGEM network described herein are currently part of a groundwater level monitoring program conducted by MCWRA. As part of the existing monitoring programs, reference points (RP) have been established for all of the wells. To ensure consistency in measuring depth to water, a description of each well's RP is recorded in a field data collection notebook. In many cases, photographs have also been taken of the RP. Reference point elevations have been determined for all wells that are currently in a monitoring program; this data is listed in Appendix A.

A reference point will be determined for any new wells that are brought into the CASGEM network. Reference point elevations are determined using a digital elevation model from the United States Geological Survey (USGS) with a cell size of 32 feet by 32 feet.

Figure 10 – Distribution of Seasonal High Groundwater Elevations by Month

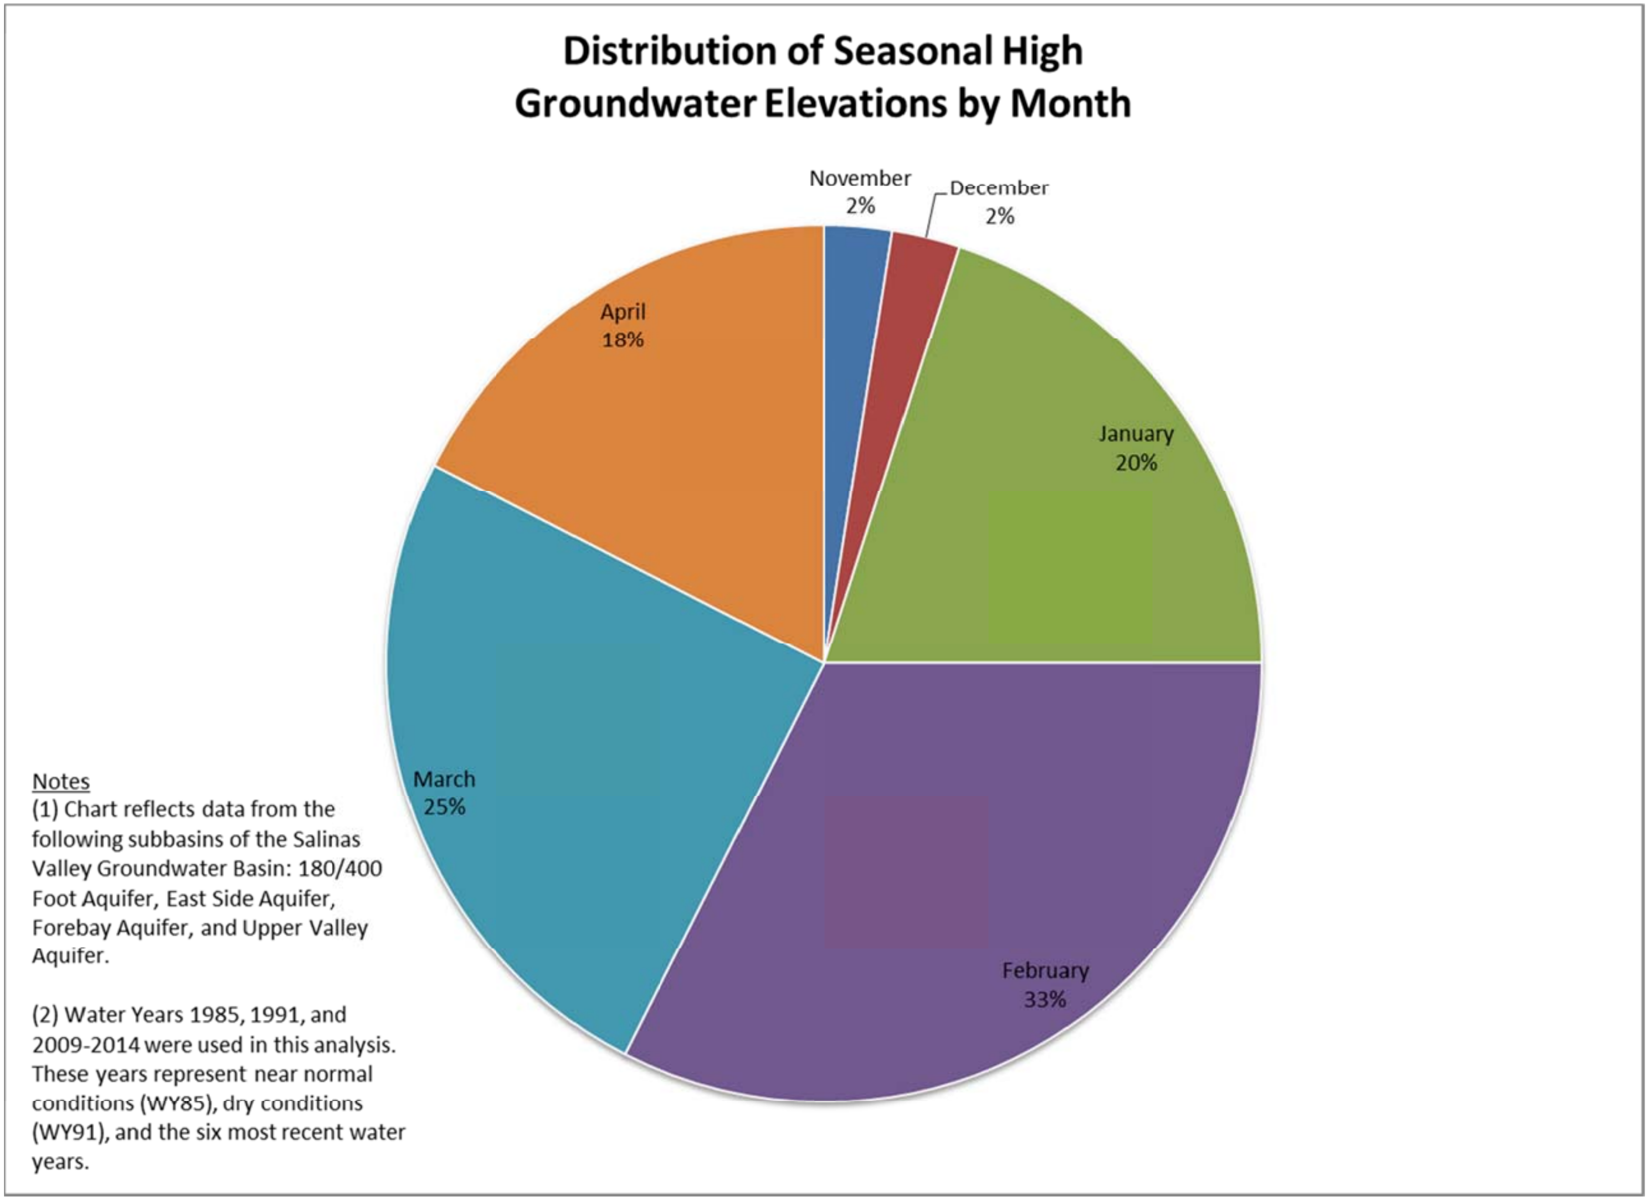

Figure 11 – Distribution of Seasonal Low Groundwater Elevations by Month

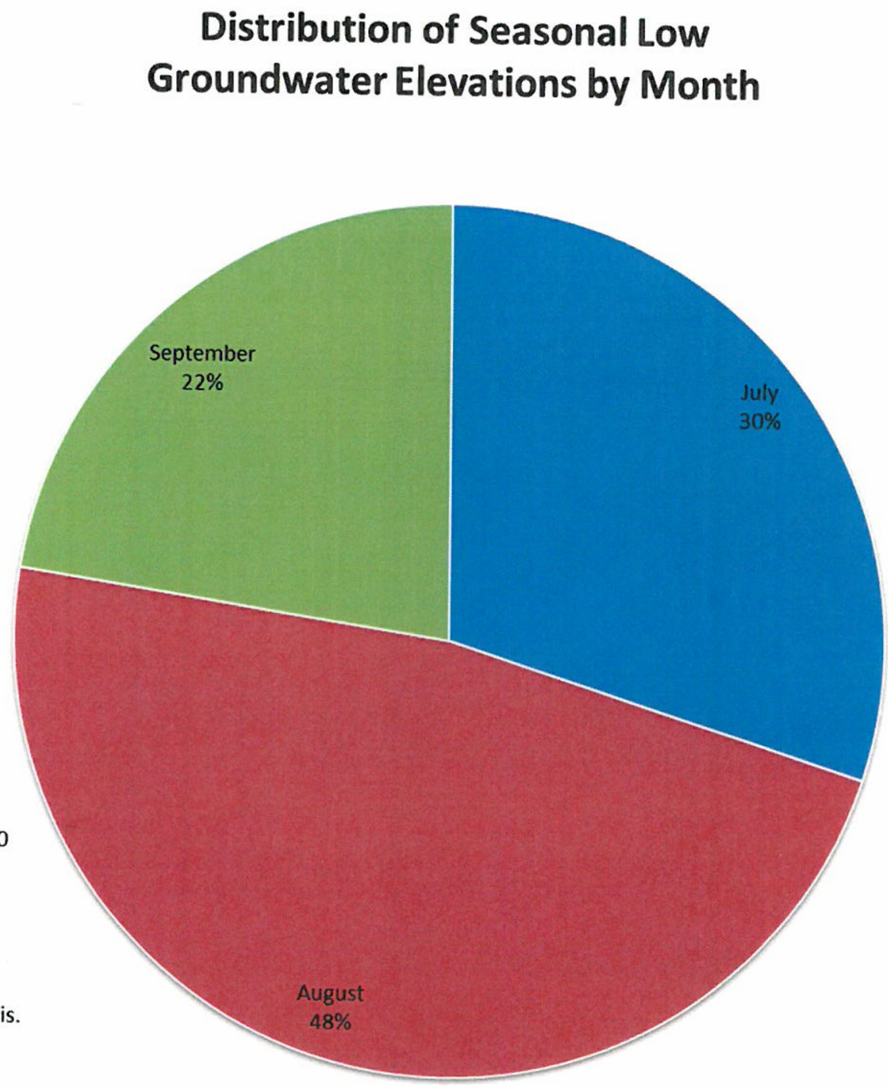

Notes

(1) Chart reflects data from the following subbasins of the Salinas Valley Groundwater Basin: 180/400 Foot Aquifer, East Side Aquifer, Forebay Aquifer, and Upper Valley Aquifer.

(2) Water Years 1985, 1991, and 2009-2014 were used in this analysis. These years represent near normal conditions (WY85), dry conditions (WY91), and the six most recent water years.

4.4 Field Methods

Groundwater elevation data collected from wells in the CASGEM network is intended to reflect static conditions. Best efforts will be made to ensure that wells have not recently been pumped prior to collecting a data point. Depth to water measurements will be made using one or more of the methods discussed in the following sections. Measurement methods described in the following sections are based on the Department of Water Resources document *Groundwater Elevation Monitoring Guidelines* (December 2010) with some alterations specific to wells in the monitored basins/subbasins described in this Monitoring Plan.

4.4.1 Graduated steel tape

Prior to measurement:

- Ensure that the reference point on the well can be clearly determined. Check notes in the field data collection notebook.
- Review the notes and comments for previous measurements in the field data collection notebook to determine if there are any unique circumstances at this well.
- Take note of whether oil has previously been present at this well; this will be recorded in the comments section of the data form.

Making a measurement:

- Use the previous depth to water measurement to estimate a length of tape that will be needed.
- Lower the tape into the well, feeling for a change in the weight of the tape, which typically indicates that either (a) the tape has reached the water surface or (b) the tape is sticking to the side of the well casing.
- Continue lowering the tape into the well until the next whole foot mark is at the reference point. This value on the tape should be recorded in the field data collection notebook.
- Bring the tape to the surface and record the number of the wetted interval to the nearest foot.
- If an oil layer is present, read the tape at the top of the oil mark to the nearest foot. Note in the comments section of the data form that oil was present.
- Repeat this procedure a second time and note any differences in measurement in the field data collection notebook.

4.4.2 Electric water level meter

This method of measurement employs a battery-powered water level meter and a small probe attached to a ruled length of cable. Depth to water measurements collected using this equipment are recorded to the nearest tenth of an inch. This instrument is sometimes referred to as a "sounder".

Prior to measurement:

- Review the field data sheet for the well and note whether oil has been present at this well in the past. The electric water level meter should not be used in wells where oil is present.
- Ensure that the reference point on the well can be clearly determined. Check notes in the field data collection notebook.
- Confirm that the water level meter is functioning and is turned on so that the beeping indicator will operate properly.

Making a measurement:

- Review previous depth to water measurements for the well to estimate the length of tape that will be needed.
- Lower the electrode into the well until the indicator sounds, showing the probe is in contact with the water surface.
- Place the tape against the reference point and read the depth to water to the nearest 0.1 foot. Record this value on the field data sheet.
- Make a second measurement and note any differences in measurement in the field data collection notebook.

4.4.3 Sonic water level meter

This meter uses sound waves to measure the depth to water in a well. The meter must be adjusted to the air temperature outside the well; there is a card with reference temperatures in the case with the sonic meter.

Making a measurement:

- Insert the meter probe into the access port and push the power-on switch. Record the depth from the readout.
- Record the depth to water measurement in the field data collection notebook.

4.4.4 Pressure transducer

Automated water-level measurements are made with a pressure transducer attached to a data logger. Pressure transducers are lowered to a depth below the water level in the well and fastened to the well head at a reference point. Data points are logged on an hourly basis. MCWRA uses factory-calibrated, vented pressure transducers (Appendix D). MCWRA staff collects the pressure transducer data once per quarter. During the data collection process, data loggers are stopped, and the data is downloaded onto a laptop, and then the data logger is reactivated and scheduled to begin collecting data again on the next hour. Upon return from the field, data is processed and reviewed for errors.

4.5 Data Collection, Processing, and Reporting

Following completion of all fieldwork, data is transcribed from field data sheets and checked for errors before being loaded into MCWRA's Oracle platform database. All data will be stored in the MCWRA database before being uploaded to the CASGEM website. Submittal of data to the CASGEM website will occur at a minimum of twice per year, no later than January 1 and July 1, per DWR CASGEM program guidelines.

Bi-annual submittal of data to the CASGEM website will include the following for each well in the CASGEM network, as described in the DWR document *CASGEM Procedures for Monitoring Entity Reporting*:

- Well identification number
- Measurement date
- Reference point and land surface elevation, in feet, using NAVD88 vertical datum
- Depth to water, in feet
- Method of measuring water depth
- Measurement quality codes
- Measuring agency identification
- Comments about measurement, if applicable

The following information will also be submitted to the CASGEM online system, as it is required by DWR unless otherwise noted:

- Monitoring Entity name, address, telephone number, contact person name and email address, and any other relevant contact information
- Groundwater basins being monitored (both entire and partial basins)
- State Well Identification number (recommended)
- Decimal latitude/longitude coordinates of well (NAD83)
- Groundwater basin or subbasin
- Reference point elevation of the well, in feet, using NAVD88 vertical datum
- Elevation of land surface datum at the well, in fee, using NAVD88 vertical datum
- Use of well
- Well completion type (e.g. single well, nested well, or multi-completion well)
- Depth of screened interval(s) and total depth of well, in feet, if available
- Well Completion Report number (DWR Form 188), if available

David Eisen
United States Army Corps of Engineers
Fort Ord BRAC Office
PO Box 5008
Monterey, CA 93944-504

February 13, 2015

Dear Mr. Eisen:

On behalf of the Monterey County Water Resources Agency (MCWRA) I am writing to request the U.S. Army Corps of Engineers' voluntary participation in the California Statewide Groundwater Elevation Monitoring (CASGEM) program.

On November 4, 2009, the State Legislature amended the California Water Code with Senate Bill SBx7-6, which resulted in development of the CASGEM program by the California Department of Water Resources (DWR). As part of the CASGEM program, MCWRA is the designated Monitoring Entity for certain groundwater basins in Monterey County, including the Salinas Valley Groundwater Basin.

The U.S. Army Corps of Engineers (USACE) owns multiple parcels of land, specifically portions of the former Fort Ord, which are located in the Salinas Valley Groundwater Basin. MCWRA is seeking USACE's voluntary participation in the CASGEM program because the existing monitoring well network does not extend to this area of the groundwater basin.

MCWRA has no specific knowledge as to the location of monitoring wells on USACE property, so consent to participate in the CASGEM program would require disclosure of well information and either permission for MCWRA to access these wells or an arrangement wherein USACE would provide data to MCWRA. If USACE is considering participation, MCWRA can discuss this in more detail as needed.

As part of the CASGEM program, MCWRA would submit certain data about USACE wells to DWR for inclusion in a statewide database. The database will be available to the public for local and state entities to evaluate and monitor groundwater conditions. MCWRA will report the following to DWR for any well included in the CASGEM program:

- Depth to static (non-pumping) groundwater level, reported two times per year, beginning in 2015
- Approximate well location, within 1,000 feet of the actual well location
- Screened interval(s) and depth of the well as provided on the well log
- General category of well use (i.e. monitoring, public supply, domestic)

MCWRA sincerely appreciates your consideration of voluntary participation in the CASGEM program. Please feel free to contact MCWRA at 831-755-4860 if you have any questions. Additional information about the CASGEM program is also available from DWR at www.water.ca.gov/groundwater/casgem.

Regards,

David E. Chardavoyne

MONTEREY COUNTY WATER RESOURCES AGENCY
BOARD OF DIRECTORS

MEETING DATE:	October 27, 2014	**AGENDA ITEM:**	
AGENDA TITLE:	RECEIVE REPORT ON SALINAS VALLEY WATER CONDITIONS FOR THE FOURTH QUARTER OF WATER YEAR 2013-2014		
Consent (X)	**Action ( )**	**Information ( )**	
SUBMITTED BY: **PHONE:**	Robert Johnson 755-4860	**PREPARED BY:** **PHONE:**	Peter Kwiek, Jess Barreras 755-4860
DEADLINE FOR BOARD ACTION:	October 27, 2014		

RECOMMENDED BOARD ACTION:

Receive report on Salinas Valley water conditions for the fourth quarter of Water Year 2013-2014.

PRIOR RELEVANT BOARD ACTION:

A report was last presented to the Board on September 22, 2014, covering the third quarter of Water Year 2013-2014.

DISCUSSION/ANALYSIS:

This report covers the fourth quarter of Water Year 2013-2014 (WY14), July through September, 2014. It provides a brief overview of water conditions in the Salinas Valley with discussion of precipitation, reservoir storage, and ground water level trends. Data for each of these components are included as graphs and tables in Attachments A through I.

Precipitation – The fourth quarter of WY14 brought less than normal rainfall to Salinas and King City. Cumulative totals for the quarter were 0.11 inches (55% of normal rainfall for the quarter) at the Salinas Airport, while no measurable rainfall was logged in King City, which, on average, receives a total of 0.17 inches during the months of July through September.

Attachment A contains graphs for both stations showing monthly and cumulative precipitation data for the current and a normal water year. Tables with precipitation values shown on the graphs and percent of normal precipitation are also presented in Attachment A.

Rainfall data for Salinas and King City should be considered preliminary until verified by National Weather Service data at a later date.

Reservoirs - The following table compares fourth quarter storage at Nacimiento and San Antonio reservoirs for the past two years. Storage in Nacimiento Reservoir is 46,763 acre-feet lower than in September 2013, while storage in San Antonio Reservoir is 8,547 acre-feet lower.

Reservoir	**September 30, 2014 (WY14) Storage in acre-feet**	**September 30, 2013 (WY13) Storage in acre-feet**	**Difference in acre-feet**
Nacimiento	63,850	110,613	-46,763
San Antonio	12,266	20,813	-8,547

Graphs for both reservoirs showing daily storage for the last five water years and average daily storage are included as Attachments B and C.

Ground Water Levels – More than 80 wells are measured monthly throughout the Salinas Valley to monitor seasonal ground water level fluctuations. Data from approximately 50 of these wells is used in the preparation of this report. The measurements are categorized by hydrologic subarea, averaged, and graphed to compare current water levels with selected past conditions. Graphs for individual subareas, showing the current year's water level conditions, last year's conditions (WY13), dry conditions (WY91), and near-normal conditions (WY85), are found in Attachments D through H. Attachment I is a summary of water level changes for all subareas.

Ground water level measurements indicate that, by the end of the fourth quarter of WY14, water levels were recovering in the Pressure and East Side Subareas, but not in the Forebay or Upper Valley Subareas. Over the past month, average ground water levels rose by four feet in the Pressure 180-Foot Aquifer, two feet in the Pressure 400-Foot Aquifer, and one foot in the East Side Subarea while declining by two feet in the Forebay Subarea and one foot in the Upper Valley Subareas.

Compared to September 2013, average ground water levels in September 2014 were eight to twelve feet lower in all subareas, as shown in Attachment I.

When compared to WY85, which is considered to be a year of near normal ground water conditions, current water levels are 25 feet lower in the East Side Subarea, 10 feet lower in the Pressure 180-Foot Aquifer, eight feet lower in the Forebay Subarea and six feet lower in the Upper Valley Subarea. Water levels in the Pressure 400-Foot Aquifer are two feet higher than in WY85.

Average ground water levels for the fourth quarter of WY14 have fallen to WY91 levels in the Forebay Subarea, while falling below WY91 levels in both the East Side and Upper Valley Subareas. In the Pressure 180-Foot Aquifer, water levels equaled WY91 levels in August 2014 before recovering by two feet by the end of the quarter. By contrast, throughout the fourth quarter, water levels in the Pressure 400-Foot Aquifer remained eight to 10 feet higher than in WY91.

Generalized Ground Water Trends
September 2014

Area	September 2014 Depth to Water	1 Year Change	Change From WY 1985	1 Month Change
Pressure 180-Foot Aquifer	62'	down 8'	down 10'	up 4'
Pressure 400-Foot Aquifer	55'	down 7'	up 2'	up 2'
East Side Subarea	157'	down 12'	down 25'	up 1'
Forebay Subarea	81'	down 10'	down 8'	down 2'
Upper Valley Subarea	55'	down 8'	down 6'	down 1'

September water levels, compared to last year, range from 12' lower to 7' lower.

September water levels, compared to WY 1985, range from 25' lower to 2' higher.

September changes in water levels over the last month range from 2' lower to 4' higher.

In-Situ Inc.

Innovations in Water Monitoring

Level **TROLL**® 400, 500 & 700 Data Loggers

Get water level data the way you want it, when you want it with industry-leading water level/pressure and temperature data loggers. By partnering with In-Situ® Inc., you receive durable Level TROLL® Data Loggers that provide years of service, accurate results, intuitive software, and real-time functionality.

Be Effective

- **Increase productivity:** Reduce training and installation time with In-Situ Inc.'s intuitive software platform and integrated components. Patented twist-lock connectors, included on Level TROLL Loggers and RuggedCable® Systems, ensure error-free deployments.
- **Set up real-time networks:** Access data 24/7 and receive event notifications when you connect data loggers to telemetry systems, radios, or other third-party data collection platforms. Control gates, pumps, alarms, and other equipment by using built-in Modbus/RS485, SDI-12, or 4-20 mA communication protocols.
- **Streamline analysis and reporting**: Automate water level corrections and post-processing, graph data, and accelerate report generation with Win-Situ® Software. Easily export data to Excel®, a web-based management service, or data analysis software.

Be Reliable

- **Deploy in all environments:** Install loggers in fresh water, saltwater, and contaminated waters. Solid titanium, sealed construction outperforms and outlasts specially-coated data loggers.
- **Log accurate data:** Get optimal accuracy under all operating conditions. Sensors undergo NIST®-traceable factory calibration across the full pressure and temperature range. For applications requiring the highest levels of accuracy, use a vented (gauged) system.
- **Get long-lasting operation:** Reduce trips to the field with low-power loggers that typically operate for 10 years.

Be In-Situ

- Receive **free**, 24/7 technical support and online resources.
- Order data loggers and accessories from the In-Situ e-store.
- Get guaranteed 7-day service for maintenance (U.S.A. only).

Applications

- Aquifer characterization: slug tests & pumping tests
- Coastal: tide/harbor levels & wetland/estuary research
- Hydrologic events: crest stage gages, storm surge monitoring, & flood control systems
- Long-term, real-time groundwater & surface water monitoring
- Mining & remediation

Every Application & Budget

Use maintenance-free, non-vented systems for long-term monitoring and at flood-prone or high-humidity sites.

Use high-accuracy, vented systems to conduct aquifer tests and to view barometrically compensated water level data in real time.

Forgot to set a level reference at the beginning of a deployment? Automate level corrections by using Win-Situ Software's post-level correction Wizard.

BaroTROLL® Data Logger

Using a non-vented system? Collect barometric pressure and temperature data with a titanium BaroTROLL Data Logger in order to compensate data for barometric pressure fluctuations.

Calculating barometric efficiency? Use the BaroTROLL Logger with vented systems.

Win-Situ® Baro Merge® Software automates post correction of water level data.

Specifications are subject to change without notice.

Figures

Tables

Introduction

The Monterey Peninsula Water Management District (MPWMD or District) is participating in the California Statewide Groundwater Elevation Monitoring Program (CASGEM) which is administered by the Department of Water Resources (DWR). This groundwater monitoring plan lays the foundation for this monitoring effort and provides information on the wells to be sampled, monitoring schedule, and the characteristics of the groundwater basins. This plan contains two parts because MPWMD will be providing monitor well data from the Seaside Groundwater Basin as well as the Carmel Valley Alluvial Aquifer under the CASGEM.

Regional Geologic Setting for the Seaside Groundwater Basin

Water Bearing Formations

The Seaside Groundwater Basin consists of a sedimentary sequence of water-bearing materials that overlie the relatively impermeable Monterey Formation of Miocene age and older crystalline rocks. From oldest to youngest, the water-bearing units of the Seaside Basin are the Miocene Santa Margarita Sandstone (Tsm), the Tertiary and Quaternary "continental deposits" (QTc), and the Pleistocene and Holocene Aromas Sand and Older Dunes (Qe and Qt) (Yates and others 2005 and GTC 1986).

The Santa Margarita Sandstone corresponds to the "Santa Margarita Aquifer" and is a loose to weakly-cemented, marine sandstone with stratigraphic thickness up to approximately 300 feet. The upper portion of this deposit is medium-grained clean sand. With increasing depth and proximity to the underlying Monterey Formation, the clay content of the unit increases (Yates and others 2005).

The continental deposits correspond to the "Paso Robles Aquifer" and consist of a complex sequence of interbedded sand, gravel, and clay deposits. These deposits are more than 600 feet thick in some portions of the basin. The water-bearing portions of the continental deposits are thick lenses of sand and gravel of limited areal extent (Yates and others 2005).

The Aromas Sand and Older Dunes are surficial deposits that are of minor importance in the basin. The deposits are unconfined, in direct hydraulic communication with the ocean, and are only saturated in the extreme coastal portion of the basin (Yates and others 2005).

Surface outcrops within the area are limited primarily to alluvial sands and terrace deposits. Small areas of the Paso Robles and Santa Margarita Aquifers outcrop in the eastern portion of the Seaside Basin.

)

Restrictive Structures

Structural deformation of the basin has resulted in varying thickness and depths of all of the geologic units across the basin (Yates and others 2005, GTC 1986, and DWR 1974). Basin structure is relatively well understood in the Laguna Seca and coastal subareas where production wells are numerous. Subsurface information in those areas reveals a complex arrangement of faults, anticlines, and synclines. Prominent among them is the Laguna Seca Anticline that uplifts the Monterey Formation and forms the boundary between the northern and southern subbasins. The Paso Robles and the Santa Margarita Aquifers thicken toward the eastern end of the southern subbasin as a result of a syncline. The Seaside and Ord Terrace faults create abrupt increases in basin thickness within the coastal parts of the southern and northern subbasins.

In the Seaside Basin, faults are associated with abrupt changes in basin thickness but appear to have little effect on groundwater flow where permeable units are present on both sides of the fault. All of the faults are steep normal or reverse faults, and most of them exhibit a combination of horizontal displacement (right-lateral) and vertical displacement (downthrown block on the north). All of them trend southeast-northwest. The Chupines fault forms the southern boundary of the basin where it juxtaposes relatively impermeable units of the Monterey Formation against the Santa Margarita Sandstone and continental deposits. The next fault to the north – the Seaside fault – passes obliquely through the southern subbasin. It is associated with as much as 500 feet of vertical displacement of the top of the Monterey Formation and it truncates the southern extent of the Santa Margarita Sandstone and continental deposits. Groundwater appears to flow freely across the Seaside fault in shallow aquifer horizons. Farther north, the Ord Terrace fault is similar to the Seaside fault, with as much as 450 feet of displacement of the top of the Monterey Formation. Neither the Seaside nor Ord Terrace faults are a significant barrier to groundwater flow.

The Seaside Basin does not appear to have a regional confining layer equivalent to the Salinas Valley Aquiclude that overlies the 180-Foot Aquifer throughout most of the coastal part of the Salinas Valley. The first clay layers encountered in the boreholes for four monitoring wells installed by MPWMD between Seaside and the Main Garrison area on the former Fort Ord are thin (less than 20 feet) and of inconsistent elevation.

Based on calibration of a groundwater flow model of the Laguna Seca area (the eastern part of the southern subbasin), the hydraulic conductivities for the Paso Robles and Santa Margarita Aquifers were estimated to be 2 ft/day and 3-5 ft/day, respectively. Similarly, calibrated storativity values were estimated to be 0.08 in unconfined aquifers and 0.0006 in confined aquifers.

Recharge Areas

The largest native sources of recharge to the basin are deep percolation of rainfall, irrigation water, and pipe leaks (Yates and others 2005, GTC 1986, and Muir 1982). This recharge occurs throughout the basin and is facilitated by the generally sandy soils. Septic system leach fields also contribute small amounts of groundwater recharge. The largest non-native source of recharge to the basin is by groundwater recharge via injection wells. Since 1998, MPWMD has injected over 4,300 acre-feet into specialized Aquifer Storage and Recovery (ASR) wells the northern subbasin.

A significant percentage of groundwater yield near the coast consists of groundwater inflow from inland areas. In addition, groundwater can flow to or from offshore areas depending on the elevation of groundwater levels near the coast. If coastal water levels are below sea level, groundwater flows onshore (landward). Initially, this onshore flow may not be salty if offshore parts of the aquifer still contain residual freshwater from previous decades when groundwater flow was greater or past periods when sea levels were lower. It is estimated that approximately 1,100 acre-feet of onshore flow from the offshore part of the Santa Margarita Aquifer occurred in 2002 (Yates and others 2005).

Groundwater Level Trends

Groundwater level monitoring in production and monitoring wells within the basin has generally shown declines in the period from the 1960's to the present. Most groundwater extraction in the Seaside Basin is from the coastal part of the northern subbasin. Hydrographs for that area show a significant decline in water levels in almost all wells in the Santa Margarita Aquifer since 1995. In many of these wells, water levels were consistently above sea level prior to 1995 and are now consistently below sea level. The net decline in spring water levels between 1995 and 2002 was 10-15 feet in many wells, and the amount of seasonal drawdown from spring to fall each year has also increased from less than 5 feet to 15 feet (Yates and others 2005). The hydrographs for some wells in the Paso Robles Aquifer have also been declining, while others have been rising. These patterns are more strongly related to groundwater extraction than to climatic conditions.

Groundwater Storage

The storage capacity of the Seaside Groundwater Basin was estimated to be 564,700 acre-feet in 1990 (SGD 1990). This estimate included a component for offshore storage and assumed a weighted average specific yield value of 12%. Of this total, the estimated storage for the onshore parts of the coastal subareas was 162,300 acre-feet, with 9,000 acre-feet estimated to be above sea level. More recent storage capacity estimates based on a specific yield value of 8% suggest that the amount of usable groundwater storage capacity in the coastal area of the basin is 6,200 acre-feet (Yates and others 2005).

Monitoring Plan Rationale

Monitor wells selected for CASGEM monitoring are distributed to give a good representation of groundwater conditions of the Seaside Groundwater Basin. However, it should be noted that large areas of the basin do not have adequate monitor well coverage due to the lack of historical development and land-use restrictions (i.e., inland firing ranges of the former Fort Ord).

Well Network

The well network consists of 22 wells located primarily in and near the coastal subareas of the Seaside Groundwater Basin. Many of these wells are paired and labeled deep and shallow to represent where they are screened in the aquifer. The list of monitoring wells for the Seaside Ground Water Basin is provided in Table 1. It is our understanding that Monterey County Water Resources Agency will be reporting on monitor wells that are located in and near the inland portions of the basin.

Monitoring Schedule

Wells for the CASGEM program will be monitored twice a year, once at the end of September and once at the end of March.

Description of Field Methods

Depth to the water table is measured directly with electric measuring tape to the nearest hundredth of a foot.

NOTES:
1. Well Numbers are unofficial designations; not verified with DWR-assigned well numbers.
2. Geologic Unit refers to the unit adjacent to the screened interval: Qod/Qar = Quaternary "Older Dunes and Aromas Sand" (Dune aquifer); QTc = Tertiary and Quaternary "continental deposits" (Paso Robles aquifer); Tsm = Tertiary "Santa Margarita Sandstone" (Santa Margarita aquifer); Tp = "Purisima Formation"; and Tm = "Monterey Formation".
3. Elevation = reference point elevation at the wellhead: (e1) = estimated with Paulin altimeter; (e2) = estimated from topo map; (s1) = surveyed by Land Data Services (LDS) (Jul 20, 1990); (s2) = surveyed by LDS (Aug 27, 1992); (s3) = surveyed by Sandis Humber Jones (1995 and 1997); (s4) = surveyed, source uncertain; (s5) = surveyed by MPWMD (Jun 6, 1997).
4. "- -" in a blank cell means not applicable or not available. "- -" in a Screened Interval cell indicates multiple screen intervals.
5. Data Type refers to MPWMD data collected: wl = water level; wq = water quality.
6. Well completion data at sites MPWMD #FO-01, 2, and 3 are documented in "Fort Ord Ground Water Monitoring Well Project", Staal, Gardner & Dunne, Inc. (SGD), Jan 1987.
7. Well completion data at site MPWMD #FO-04 are documented in "Supplemental Hydrogeologic Assessment, Monterey Research Park, Laguna Seca Subarea", SGD, Nov 1988.
8. Well completion data at site MPWMD #FO-05 and 6 are documented in "Laguna Seca Ranch, Supplemental Hydrogeologic Assessment", SGD, Jul 12, 1991.
9. Well completion data for MSC, PCA-W, PCA-E, Plumas '90 Test and Paralta Test sites are documented in individual reports for each of these sites, SGD, Jul 1990.
10. Well completion data for Justin Court site are documented in "Additional Investigations of Ryan Ranch's Water Supply", John Logan, Jun 27, 1981.
11. Well completion data for LS Pistol Range, York Rd-West, Seca Place, and Robley Rd sites are documented in "Phase II Hydrogeologic Investigation, Laguna Seca Subarea", SGD, Sep 1988.
13. Well completion data for LS Driving Range (SCS Deep) and LS No. 1 Subdivision sites are listed in Appendix B of "Phase II Hydrogeologic Investigation, Laguna Seca Subarea", SGD, Sep 1988.
14. Geologic unit picks for MPWMD FO-09 and FO-10 sites from Feeney and Rosenberg, Mar 31, 2003 (Figure 4).
15. The well at the location of "Blue Larkspur-East End" has been described in LSS Phase II and III reports as "LSR '59 Pond Test". However, based on information and notes from DWR Log #43668, it appears that "LSR '59 Pond Test" well has been misinterpreted to be located at the east end of Blue Larkspur Lane. Accordingly, well completion data for "Blue Larkspur-East End" are not known.
16. In addition to the wells shown in this table, the MPWMD utilizes water level data from selected CAW production wells as part of its monthly groundwater storage tracking program in the coastal subareas of the basin.
17. It should be noted that the Seaside Basin Watermaster conducted a wellhead elevation survey of monitor and production wells in 2008. Please see MPWMD Seaside Basin Watertmaster Memorandum 2008-05 for updated wellhead reference elevation data.

Regional Geologic Setting for the Carmel Valley Alluvial Aquifer

The 36-mile-long Carmel River drains 255 square miles of the central coast of California (Figure 2). The watershed includes the Santa Lucia Mountains to the south and the Sierra del Salinas to the north. Bedrock in the basin is mainly Sur Series crystalline rock (granite, gneiss, schist) or Monterey Shale with significant outcrops of sandstone and volcanics (Page and Mathews, 1984). Mean annual rainfall varies from about 14 inches along the northeast perimeter of the basin to over 40 inches in the high peaks (up to approximately 5,000 feet in elevation) of the southern portion (James, 1999). Upper reaches on the Carmel River flow through steep-sided canyons, while the lower 16 miles is a relatively flat alluvial valley to the ocean that ranges in width from 300 to 4,500 feet. The average annual runoff at the San Clemente Dam site is 69,200 acre-feet (James, 1999). Bankfull flow is 2,200 cubic feet per second (cfs) near the mouth. On March 10, 1995, the river peaked at 16,000 cfs, which is the largest recorded (gaged) event on the Carmel River.

The unconsolidated sediments of the younger alluvium is the most significant water bearing unit in the Carmel Valley Alluvial Aquifer (Figure 2). The valley floor is composed of Holocene age poorly consolidated boulders, gravel, sand, and silt deposited by the Carmel River. Clay layers are thin and uncommon. However, silt becomes more common in the lower part of the valley. Aquifer thickness ranges from 30 feet at the drainage basin narrows to about 180 feet 1 mile upstream from the Carmel River lagoon (Kapple, 1984).

Recharge to the aquifer comes primarily through river infiltration which is about 85 percent of the net recharge. During normal to above normal rainfall years the water table recovers completely from the dry seasonal lows.

Historical Water Levels for the Carmel Valley Alluvial Aquifer

In general, the water table of the Carmel Valley Alluvial Aquifer recovers fairly rapidly with the onset of the rainy season and an increase in stream flow. For example, after the two year drought of 1976-1977, precipitation that began in January of 1978 caused water levels to recover by February 1978 (Kapple, 1984).

Monitoring Plan Rationale

Monitor wells selected for CASGEM monitoring are distributed to give a good representation of groundwater conditions of Carmel Valley Alluvial Aquifer.
